Functional Description^[1]

The CY62138CV25/30/33 and CY62138CV are high-performance CMOS static RAMs organized as 256K words by eight

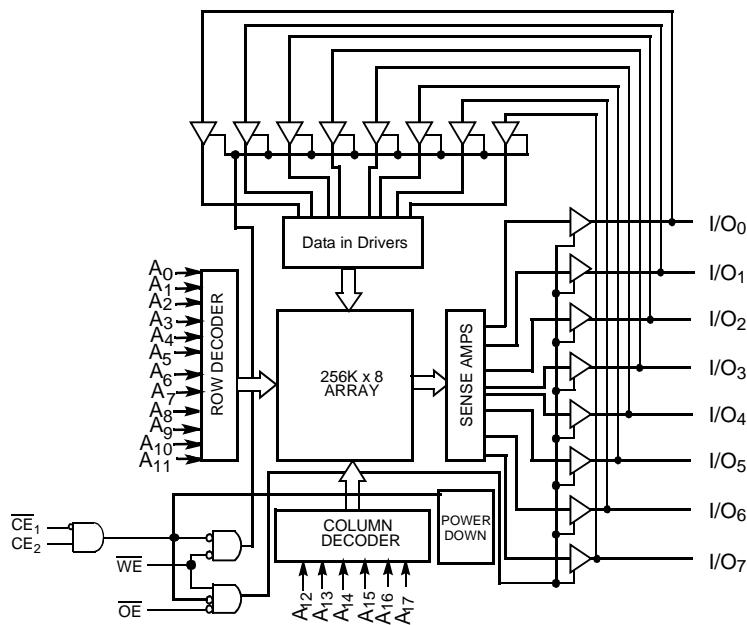

bits. This device features advanced circuit design to provide ultra-low active current. This is ideal for providing More Battery Life™ (MoBL®) in portable applications. The device also has an automatic power-down feature that significantly reduces power consumption by 80% when addresses are not toggling. The device can be put into standby mode reducing power consumption by more than 99% when deselected (CE₁ HIGH or CE₂ LOW).

Writing to the device is accomplished by taking Chip Enable 1 (CE₁) and Write Enable (WE) inputs LOW and Chip Enable 2 (CE₂) HIGH. Data on the eight I/O pins (I/O₀ through I/O₇) is then written into the location specified on the address pins (A₀ through A₁₇).

Reading from the device is accomplished by taking Chip Enable 1 (CE₁) and Output Enable (OE) LOW while forcing Write Enable (WE) and Chip Enable 2 (CE₂) HIGH. Under these conditions, the contents of the memory location specified by the address pins will appear on the I/O pins.

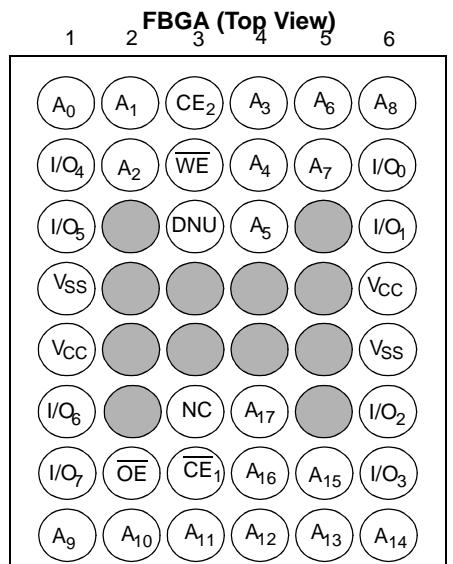

The eight input/output pins (I/O₀ through I/O₇) are placed in a high-impedance state when the device is deselected (CE₁ HIGH or CE₂ LOW), the outputs are disabled (OE HIGH), or during a write operation (CE₁ LOW, CE₂ HIGH and WE LOW). See the truth table at the back of this data sheet for a complete description of read and write modes.

Notes:

7. Full-device AC operation requires linear V_{CC} ramp from V_{DR} to V_{CC(min.)} ≥ 100 μs or stable at V_{CC(min.)} ≥ 100 μs.
8. Test conditions assume signal transition time of 5 ns or less, timing reference levels of V_{CC(typ.)}/2, input pulse levels of 0 to V_{CC(typ.)}, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
9. At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any given device.
10. t_{HZOE}, t_{HZCE}, and t_{HZWE} transitions are measured when the outputs enter a high-impedance state.
11. The internal write time of the memory is defined by the overlap of WE, CE₁ = V_{IL}, and CE₂ = V_{IH}. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input set-up and hold timing should be referenced to the edge of the signal that terminates the write.
