

UHF ASK Receiver

Description

The U3745BM is a multi-chip PLL receiver device supplied in an SO20 package. It has been specially developed for the demands of RF low-cost data transmission systems with low data rates from 1 kBaud to 10 kBaud in Manchester or Bi-phase code. The receiver is well suited to operate with Atmel Wireless & Microcontrollers' PLL RF transmitter U2745B. It can be used in the frequency receiving range of $f_0 = 310 \text{ MHz}$ to 440 MHz for ASK

data transmission. All the statements made below refer to 433.92-MHz and 315-MHz applications.

The main applications of the U3745BM are in the areas of outside temperature metering, socket control, garage door opener, consumption metering, light/ fan or air-condition control, jalousies, wireless keyboard and various other consumer market applications.

Features

- Supply voltage 4.5 V to 5.5 V, operating temperature range -40°C to 85°C
- Minimal external circuitry requirements, no RF components on the PC board except matching to the receiver antenna
- High sensitivity, especially at low data rates
- Sensitivity reduction possible even while receiving
- Fully integrated VCO
- Low power consumption due to configurable self polling with a programmable timeframe check
- Single-ended RF input for easy matching to $\lambda/4$ antenna or printed antenna on PCB
- Low-cost solution due to high integration level
- ESD protection according to MIL-STD. 883 (4KV HBM) except Pin POUT (2KV HBM)
- High image frequency suppression due to 1 MHz IF in conjunction with a SAW front-end filter. Up to 40 dB is thereby achievable with newer SAWs.
- Programmable output port for sensitivity selection or for controlling external periphery
- Communication to μC possible via a single, bi-directional data line
- Power management (polling) is also possible by means of a separate pin via the μC

Figure 3. Block diagram

RF Front End

The RF front end of the receiver is a heterodyne configuration that converts the input signal into a 1-MHz IF signal. According to figure 3, the front end consists of an LNA (low noise amplifier), LO (local oscillator), a mixer and RF amplifier.

The LO generates the carrier frequency for the mixer via a PLL synthesizer. The XTO (crystal oscillator) generates the reference frequency f_{XTO} . The VCO (voltage-controlled oscillator) generates the drive voltage frequency f_{LO} for the mixer. f_{LO} is dependent on the voltage at Pin LF. f_{LO} is divided by factor 64. The divided frequency is compared to f_{XTO} by the phase frequency detector. The current output of the phase frequency detector is connected to a passive loop filter and thereby generates the control voltage V_{LF} for the VCO. By means of that con-

figuration, V_{LF} is controlled in a way that $f_{LO}/64$ is equal to f_{XTO} . If f_{LO} is determined, f_{XTO} can be calculated using the following formula:

$$f_{\text{XTO}} = f_{\text{LO}}/64$$

The XTO is a one-pin oscillator that operates at the series resonance of the quartz crystal. According to figure 4, the crystal should be connected to GND via a capacitor CL. The value of that capacitor is recommended by the crystal supplier. The value of CL should be optimized for the individual board layout to achieve the exact value of f_{XTO} and hereby of f_{LO} . When designing the system in terms of receiving bandwidth, the accuracy of the crystal and the XTO must be considered.

Figure 4. PLL peripherals

The passive loop filter connected to Pin LF is designed for a loop bandwidth of $B_{Loop} = 100$ kHz. This value for B_{Loop} exhibits the best possible noise performance of the LO. Figure 4 shows the appropriate loop filter components to achieve the desired loop bandwidth. If the filter components are changed for any reason, please note that the maximum capacitive load at Pin LF is limited. If the capacitive load is exceeded, a bitcheck may no longer be possible since f_{LO} cannot settle in time before the bitcheck starts to evaluate the incoming data stream. Self polling does therefore also not work in that case.

f_{LO} is determined by the RF input frequency f_{RF} and the IF frequency f_{IF} using the following formula:

$$f_{LO} = f_{RF} - f_{IF}$$

To determine f_{LO} , the construction of the IF filter must be considered at this point. The nominal IF frequency is $f_{IF} = 1$ MHz. To achieve a good accuracy of the filter's corner frequencies, the filter is tuned by the crystal frequency f_{XTO} . This means that there is a fixed relation between f_{IF} and f_{LO} , that depends on the logic level at pin mode. This is described by the following formulas:

$$\text{MODE} = 0 \text{ (USA)} \quad f_{IF} = \frac{f_{LO}}{314}$$

$$\text{MODE} = 1 \text{ (Europe)} \quad f_{IF} = \frac{f_{LO}}{432.92}$$

The relation is designed to achieve the nominal IF frequency of $f_{IF} = 1$ MHz for most applications. For applications where $f_{RF} = 315$ MHz, MODE must be set to '0'. In the case of $f_{RF} = 433.92$ MHz, MODE must be set to '1'. For other RF frequencies, f_{IF} is not equal to 1 MHz. f_{IF} is then dependent on the logical level at Pin MODE and on f_{RF} . Table 1 summarizes the different conditions.

The RF input either from an antenna or from a generator must be transformed to the RF input Pin LNA_IN. The input impedance of that pin is provided in the electrical parameters. The parasitic board inductances and capacitances also influence the input matching. The RF receiver U3745BM exhibits its highest sensitivity at the best signal-to-noise ratio in the LNA. Hence, noise matching is the best choice for designing the transformation network.

A good practice when designing the network is to start with power matching. From that starting point, the values of the components can be varied to some extent to achieve the best sensitivity.

If a SAW is implemented into the input network, a mirror frequency suppression of $\Delta P_{Ref} = 40$ dB can be achieved. There are SAWs available that exhibit a notch at $\Delta f = 2$ MHz. These SAWs work best for an intermediate frequency of $f_{IF} = 1$ MHz. The selectivity of the receiver is also improved by using a SAW. In typical automotive applications, a SAW is used.

Figure 5 shows a typical input matching network for $f_{RF} = 315$ MHz and $f_{RF} = 433.92$ MHz using a SAW. Figure 6 illustrates an according input matching to 50Ω without a SAW. The input matching networks shown in figure 6 are the reference networks for the parameters given in the electrical characteristics.

Table 1. Calculation of LO and IF frequency

Conditions	Local Oscillator Frequency	Intermediate Frequency
$f_{RF} = 315$ MHz, MODE = 0	$f_{LO} = 314$ MHz	$f_{IF} = 1$ MHz
$f_{RF} = 433.92$ MHz, MODE = 1	$f_{LO} = 432.92$ MHz	$f_{IF} = 1$ MHz
$300 \text{ MHz} < f_{RF} < 365 \text{ MHz}$, MODE = 0	$f_{LO} = \frac{f_{RF}}{1 + \frac{1}{314}}$	$f_{IF} = \frac{f_{LO}}{314}$
$365 \text{ MHz} < f_{RF} < 450 \text{ MHz}$, MODE = 1	$f_{LO} = \frac{f_{RF}}{1 + \frac{1}{432.92}}$	$f_{IF} = \frac{f_{RF}}{432.92}$

Figure 5. Input matching network with SAW filter

Figure 6. Input matching network without SAW filter

Please note that for all coupling conditions (see figures 5 and 6), the bond wire inductivity of the LNA ground is compensated. C3 forms a series resonance circuit together with the bond wire. L = 25 nH is a feed inductor to establish a DC path. Its value is not critical but must be large enough not to detune the series resonance circuit. For cost reduction, this inductor can be easily printed on the PCB. This configuration improves the sensitivity of the receiver by about 1 dB to 2 dB.

Analog Signal Processing

IF Amplifier

The signals coming from the RF front end are filtered by the fully integrated 4th-order IF filter. The IF center frequency is $f_{IF} = 1 \text{ MHz}$ for applications where $f_{RF} = 315 \text{ MHz}$ or $f_{RF} = 433.92 \text{ MHz}$ is used. For other

RF input frequencies, refer to table 1 to determine the center frequency.

The receiver U3745BM employs an IF bandwidth of $B_{IF} = 600 \text{ kHz}$. This IC can be used together with the U2745B. SAW transmitters exhibit much higher transmit frequency tolerances compared to PLL transmitters. Generally, it is necessary to use $B_{IF} = 600 \text{ kHz}$ together with such transmitters.

RSSI Amplifier

The subsequent RSSI amplifier enhances the output signal of the IF amplifier before it is fed into the demodulator. The dynamic range of this amplifier is $DR_{RSSI} = 60$ dB. If the RSSI amplifier is operated within its linear range, the best S/N ratio is maintained in ASK mode. If the dynamic range is exceeded by the transmitter signal, the S/N ratio is defined by the ratio of the maximum RSSI output voltage and the RSSI output voltage due to a disturber. The dynamic range of the RSSI amplifier is exceeded if the RF input signal is about 60 dB higher compared to the RF input signal at full sensitivity.

Since different RF input networks may exhibit slightly different values for the LNA gain, the sensitivity values given in the electrical characteristics refer to a specific input matching. This matching is illustrated in figure 6 and exhibits the best possible sensitivity.

Demodulator and Data Filter

The signal coming from the RSSI amplifier is converted into the raw data signal by the ASK demodulator.

In ASK mode, an automatic threshold control circuit (ATC) is employed to set the detection reference voltage to a value where a good signal-to-noise ratio is achieved. This circuit also implies the effective suppression of any kind of inband noise signals or competing transmitters. If the S/N ratio exceeds 10 dB, the data signal can be detected properly.

The output signal of the demodulator is filtered by the data filter before it is fed into the digital signal processing circuit. The data filter improves the S/N ratio as its pass-band can be adopted to the characteristics of the data signal. The data filter consists of a 1st-order highpass and a 1st-order lowpass filter.

The highpass filter cut-off frequency is defined by an external capacitor connected to Pin CDEM. The cut-off frequency of the highpass filter is defined by the following formula:

$$f_{cu_DF} = \frac{1}{2 \times \pi \times 30 \text{ k}\Omega \times CDEM}$$

In self-polling mode, the data filter must settle very rapidly to achieve a low current consumption. Therefore, CDEM cannot be increased to very high values if self polling is used. On the other hand, CDEM must be large enough to meet the data filter requirements according to the data signal. Recommended values for CDEM are given in the electrical characteristics.

The cut-off frequency of the lowpass filter is defined by the selected baudrate range (BR_Range). BR_Range is defined in the OPMODE register (refer to chapter ‘Con-

figuration of the Receiver’). BR_Range must be set in accordance to the used baudrate.

The U3745BM is designed to operate with data coding where the DC level of the data signal is 50%. This is valid for Manchester and Bi-phase coding. If other modulation schemes are used, the DC level should always remain within the range of $V_{DC_min} = 33\%$ and $V_{DC_max} = 66\%$. The sensitivity may be reduced by up to 1.5 dB in that condition.

Each BR_Range is also defined by a minimum and a maximum edge-to-edge time (t_{ee_sig}). These limits are defined in the electrical characteristics. They should not be exceeded to maintain full sensitivity of the receiver.

Receiving Characteristics

The RF receiver U3745BM can be operated with and without a SAW front end filter. The selectivity with and without a SAW front end filter is illustrated in figure 7. This example relates to ASK mode of the U3745BM. Note that the mirror frequency is reduced by 40 dB. The plots are printed relatively to the maximum sensitivity. If a SAW filter is used, an insertion loss of about 4 dB must be considered.

When designing the system in terms of receiving bandwidth, the LO deviation must be considered as it also determines the IF center frequency. The total LO deviation is calculated to be the sum of the deviation of the crystal and the XTO deviation of the U3745BM. Low-cost crystals are specified to be within ± 100 ppm. The XTO deviation of the U3745BM is an additional deviation due to the XTO circuit. This deviation is specified to be ± 50 ppm. If a crystal of ± 100 ppm is used, the total deviation is ± 150 ppm in that case. Note that the receiving bandwidth and the IF-filter bandwidth are equivalent in ASK mode.

Figure 7. Receiving frequency response

Polling Circuit and Control Logic

The receiver is designed to consume less than 1 mA while being sensitive to signals from a corresponding transmitter. This is achieved via the polling circuit. This circuit enables the signal path periodically for a short time. During this time the bitcheck logic verifies the presence of a valid transmitter signal. Only if a valid signal is detected the receiver remains active and transfers the data to the connected μ C. If there is no valid signal present, the receiver is in sleep mode most of the time resulting in low current consumption. This condition is called polling mode. A connected μ C is disabled during that time.

All relevant parameters of the polling logic can be configured by the connected μ C. This flexibility enables the user to meet the specifications in terms of current consumption, system response time, data rate etc.

Regarding the number of connection wires to the μ C, the receiver is very flexible. It can be either operated by a single bi-directional line to save ports to the connected μ C. Or it can be operated by up to three uni-directional ports.

Basic Clock Cycle of the Digital Circuitry

The complete timing of the digital circuitry and the analog filtering is derived from one clock. According to figure 8, this clock cycle T_{Clk} is derived from the crystal oscillator (XTO) in combination with a divider. The division factor is controlled by the logical state at Pin MODE. According to chapter 'RF Front End', the frequency of the crystal oscillator (f_{XTO}) is defined by the RF input signal (f_{RFin}) which also defines the operating frequency of the local oscillator (f_{LO}).

Figure 8. Generation of the basic clock cycle

Pin MODE can now be set in accordance with the desired clock cycle T_{Clk} . T_{Clk} controls the following application-relevant parameters:

- Timing of the polling circuit including bitcheck
- Timing of the analog and digital signal processing
- Timing of the register programming
- Frequency of the reset marker
- IF filter center frequency (f_{IF0})

Most applications are dominated by two transmission frequencies: $f_{Send} = 315$ MHz is mainly used in USA, $f_{Send} = 433.92$ MHz in Europe. In order to ease the usage of all T_{Clk} -dependent parameters, the electrical characteristics display three conditions for each parameter.

- Application USA
($f_{XTO} = 4.90625$ MHz, MODE = L, $T_{Clk} = 2.0383$ μ s)
- Application Europe
($f_{XTO} = 6.76438$ MHz, MODE = H, $T_{Clk} = 2.0697$ μ s)
- Other applications
(T_{Clk} is dependent on f_{XTO} and on the logical state of Pin MODE. The electrical characteristic is given as a function of T_{Clk}).

The clock cycle of some function blocks depends on the selected baud rate range (BR_Range) which is defined in the OPMODE register. This clock cycle T_{XClk} is defined by the following formulas for further reference:

$$\begin{aligned} \text{BR_Range} &= \text{BR_Range0: } T_{XClk} = 8 \times T_{Clk} \\ &\text{BR_Range1: } T_{XClk} = 4 \times T_{Clk} \\ &\text{BR_Range2: } T_{XClk} = 2 \times T_{Clk} \\ &\text{BR_Range3: } T_{XClk} = 1 \times T_{Clk} \end{aligned}$$

Polling Mode

According to figure 5, the receiver stays in polling mode in a continuous cycle of three different modes. In sleep mode, the signal processing circuitry is disabled for the time period T_{Sleep} while consuming low current of $I_S = I_{Soff}$. During the start-up period, $T_{Startup}$, all signal processing circuits are enabled and settled. In the following bit check mode, the incoming data stream is analyzed bit by bit contra a valid transmitter signal. If no valid signal is present, the receiver is set back to sleep mode after the period $T_{Bitcheck}$. This period varies check by check as it is a statistical process. An average value for $T_{Bitcheck}$ is given in the electrical characteristics. During $T_{Startup}$ and $T_{Bitcheck}$ the current consumption is $I_S = I_{Son}$. The average current consumption in polling mode is dependent on the duty cycle of the active mode and can be calculated as:

$$I_{Spoll} = \frac{I_{Soff} \times T_{Sleep} + I_{Son} \times (T_{Startup} + T_{Bitcheck})}{T_{Sleep} + T_{Startup} + T_{Bitcheck}}$$

During T_{Sleep} and T_{Startup} , the receiver is not sensitive to a transmitter signal. To guarantee the reception of a transmitted command, the transmitter must start the telegram with an adequate preburst. The required length of the preburst is dependent on the polling parameters T_{Sleep} , T_{Startup} , T_{Bitcheck} and the startup time of a connected μC ($T_{\text{Start},\mu\text{C}}$). T_{Bitcheck} thus depends on the actual bitrate and the number of bits (N_{Bitcheck}) to be tested.

The following formula indicates how to calculate the preburst length.

$$T_{\text{Preamble}} \geq T_{\text{Sleep}} + T_{\text{Startup}} + T_{\text{Bitcheck}} + T_{\text{Start},\mu\text{C}}$$

Sleep Mode

The length of period T_{Sleep} is defined by the 5-bit word Sleep of the OPMODE register, the extension factor XSleep , according to table 10, and the basic clock cycle T_{Clk} . It is calculated to be:

$$T_{\text{Sleep}} = \text{Sleep} \times \text{XSleep} \times 1024 \times T_{\text{Clk}}$$

In US- and European applications, the maximum value of T_{Sleep} is about 60 ms if XSleep is set to 1. The time resolution is about 2 ms in that case. The sleep time can be

extended to almost half a second by setting XSleep to 8. XSleep can be set to 8 by bit $\text{XSleep}_{\text{Std}}$ or by bit $\text{XSleep}_{\text{Temp}}$ resulting in a different mode of action as described below:

$\text{XSleep}_{\text{Std}} = 1$ implies the standard extension factor. The sleep time is always extended.

$\text{XSleep}_{\text{Temp}} = 1$ implies the temporary extension factor. The extended sleep time is used as long as every bitcheck is OK. If the bitcheck fails once, this bit is set back to 0 automatically resulting in a regular sleep time. This functionality can be used to save current in presence of a modulated disturber similar to an expected transmitter signal. The connected μC is activated rarely in that condition. If the disturber disappears, the receiver switches back to regular polling and is again sensitive to appropriate transmitter signals.

According to table 7, the highest register value of Sleep sets the receiver a permanent sleep condition. The receiver remains in that condition until another value for Sleep is programmed into the OPMODE register. This function is desirable where several devices share a single data line.

Figure 9. Polling mode flow chart

Figure 10. Timing diagram for complete successful bitcheck

Bitcheck Mode

In bitcheck mode, the incoming data stream is examined to distinguish between a valid signal from a corresponding transmitter and signals due to noise. This is done by subsequent time frame checks where the distances between 2 signal edges are continuously compared to a programmable time window. The maximum count of this edge-to-edge tests before the receiver switches to receiving mode is also programmable.

Configuring the Bitcheck

Assuming a modulation scheme that contains 2 edges per bit, two time frame checks are verifying one bit. This is valid for Manchester, Bi-phase and most other modulation schemes. The maximum count of bits to be checked can be set to 0, 3, 6 or 9 bits via the variable N_{Bitcheck} in the OPMODE register. This implies 0, 6, 12 and 18 edge-to-edge checks respectively. If N_{Bitcheck} is set to a higher value, the receiver is less likely to switch to receiving mode due to noise. In the presence of a valid transmitter signal, the bitcheck takes less time if N_{Bitcheck} is set to a lower value. In polling mode, the bitcheck time is not dependent on N_{Bitcheck} . Figure 10 shows an example where 3 bits are tested successfully and the data signal is transferred to Pin DATA.

According to figure 11, the time window for the bitcheck is defined by two separate time limits. If the edge-to-edge time t_{ee} is in between the lower bitcheck limit $T_{\text{Lim_min}}$ and the upper bitcheck limit $T_{\text{Lim_max}}$, the check will be continued. If t_{ee} is smaller than $T_{\text{Lim_min}}$ or t_{ee} exceeds $T_{\text{Lim_max}}$, the bitcheck will be terminated and the receiver switches to sleep mode.

Figure 11. Valid time window for bitcheck

For best noise immunity it is recommended to use a low span between $T_{\text{Lim_min}}$ and $T_{\text{Lim_max}}$. This is achieved using a fixed frequency at a 50% duty cycle for the transmitter preburst. A '11111...' or a '10101...' sequence in Manchester or Bi-phase is a good choice concerning that advice. A good compromise between receiver sensitivity and susceptibility to noise is a time window of $\pm 25\%$ regarding the expected edge-to-edge time t_{ee} . Using preburst patterns that contain various edge-to-edge time periods, the bitcheck limits must be programmed according to the required span.

The bitcheck limits are determined by means of the formula below:

$$T_{\text{Lim_min}} = \text{Lim_min} \times T_{\text{XClk}}$$

$$T_{\text{Lim_max}} = (\text{Lim_max} - 1) \times T_{\text{XClk}}$$

Lim_min and Lim_max are defined by a 5-bit word each within the LIMIT register.

Using above formulas, Lim_min and Lim_max can be determined according to the required $T_{\text{Lim_min}}$, $T_{\text{Lim_max}}$ and T_{XClk} . The time resolution when defining $T_{\text{Lim_min}}$ and $T_{\text{Lim_max}}$ is T_{XClk} . The minimum edge-to-edge time t_{ee} ($t_{\text{DATA_L_min}}$, $t_{\text{DATA_H_min}}$) is defined according to the chapter 'Receiving Mode'. Due to this, the lower limit should be set to $\text{Lim_min} \geq 10$. The maximum value of the upper limit is $\text{Lim_max} = 63$.

Figures 12, 13 and 14 illustrate the bitcheck for the default bitcheck limits $\text{Lim_min} = 14$ and $\text{Lim_max} = 24$. When the IC is enabled, the signal processing circuits are enabled during T_{Startup} . The output of the demodulator (Dem_out) is undefined during that period. When the bitcheck becomes active, the bitcheck counter is clocked with the cycle T_{XClk} .

Figure 12 shows how the bitcheck proceeds if the bitcheck counter value CV_Lim is within the limits defined by Lim_min and Lim_max at the occurrence of a signal edge. In figure 14, the bitcheck fails as the value CV_lim is lower than the limit Lim_min. The bitcheck also fails if CV_Lim reaches Lim_max. This is illustrated in figure 15.

Figure 12. Timing diagram during bitcheck

Figure 13. Timing diagram for failed bitcheck (condition: CV_Lim < Lim_min)

 Figure 14. Timing diagram for failed bitcheck (condition: CV_Lim $\geq$ Lim_max)

Duration of the Bitcheck

If no transmitter signal is present during the bitcheck, the output of the demodulator delivers random signals. The bitcheck is a statistical process and T_{Bitcheck} varies for each check. Therefore, an average value for T_{Bitcheck} is given in the electrical characteristics. T_{Bitcheck} depends on the selected baudrate range and on T_{Clk} . A higher baudrate range causes a lower value for T_{Bitcheck} resulting in a lower current consumption for polling mode.

In the presence of a valid transmitter signal, T_{Bitcheck} is dependant on the frequency of that signal, f_{Sig} and the count of the checked bits, N_{Bitcheck} . A higher value for N_{Bitcheck} thereby results in a longer period for T_{Bitcheck} requiring a higher value for the transmitter pre-burst T_{Preburst} .

Receiving Mode

If the bitcheck has been successful for all bits specified by N_{Bitcheck} , the receiver switches to receiving mode. According to figure 11, the internal data signal is switched to Pin DATA in that case. A connected μ C can be woken up by the negative edge at Pin DATA. The receiver stays in that condition until it is switched back to polling mode explicitly.

Digital Signal Processing

The data from the demodulator (Dem_out) is digitally processed in different ways and as a result converted into the output signal data. This processing depends on the selected baudrate range (BR_Range). Figure 15 illustrates how Dem_out is synchronized by the extended clock cycle T_{XClk} . This clock is also used for the Bitcheck counter. Data can change its state only after T_{XClk} elapsed. The edge-to-edge time period t_{ee} of the Data signal as a result is always an integral multiple of T_{XClk} . The minimum time period between two edges of the data signal is limited to $t_{\text{ee}} \geq T_{\text{DATA_min}}$. This implies an efficient suppression of spikes at the DATA output. At the same time, it limits the maximum frequency of edges at DATA. This eases the interrupt handling of a connected μ C. $T_{\text{DATA_min}}$ is to some extent affected by the preceding edge-to-edge time interval t_{ee} as illustrated in figure 16. If t_{ee} is in between the specified bitcheck limits, the following level is frozen for the time period $T_{\text{DATA_min}} = t_{\text{min1}}$, in case of t_{ee} being outside that bitcheck limits $T_{\text{DATA_min}} = t_{\text{min2}}$ is the relevant stable time period.

The maximum time period for DATA to be Low is limited to $T_{\text{DATA_L_max}}$. This function ensures a finite response time during programming or switching off the receiver via Pin DATA. $T_{\text{DATA_L_max}}$ is thereby longer than the maximum time period indicated by the transmitter data stream. Figure 17 gives an example where Dem_out remains Low after the receiver has switched to receiving mode.

If the receiver is set to polling mode via Pin ENABLE, an 'L' pulse (T_{Doze}) must be issued at that pin. Figure 19 illustrates the timing of that command. After the positive edge of this pulse, the sleep time T_{Sleep} elapses. The receiver remains in sleep mode as long as ENABLE is held to 'L'. If the receiver is polled exclusively by a μC , T_{Sleep} can be programmed to 0 to enable a instantaneous response time. This command is the faster option than via Pin DATA at the cost of an additional connection to the μC .

Figure 18. Timing diagram of the OFF-command via Pin DATA

Figure 19. Timing diagram of the OFF-command via Pin ENABLE

Configuration of the Receiver

The U3745BM receiver is configured via two 12-bit RAM registers called OPMODE and LIMIT. The registers can be programmed by means of the bi-directional DATA port. If the register contents have changed due to a voltage drop, this condition is indicated by a certain output pattern called reset marker (RM). The receiver must be reprogrammed in that case. After a power-on reset (POR), the registers are set to default mode. If the receiver is operated in default mode, there is no need to program the registers.

Table 3 shows the structure of the registers. According to table 2, bit 1 defines if the receiver is set back to polling mode via the OFF command, (see chapter ‘Receiving Mode’) or if it is programmed. Bit 2 represents the register address. It selects the appropriate register to be programmed.

Table 2. Effect of Bit 1 and Bit 2 in programming the registers

Bit 1	Bit 2	Action
1	x	The receiver is set back to polling mode (OFF command)
0	1	The OPMODE register is programmed
0	0	The LIMIT register is programmed

Table 4 and the following illustrate the effect of the individual configuration words. The default configuration is highlighted for each word.

BR_Range sets the appropriate baud rate range. At the same time it defines XLim. XLim is used to define the bit-check limits T_{Lim_min} and T_{Lim_max} as shown in table 4.

POUT can be used to control the sensitivity of the receiver. In that application, POUT is set to 1 to reduce the sensitivity. This implies that the receiver operates with full sensitivity after a POR.

Table 3. Effect of the configuration words within the registers

Bit1	Bit2	Bit3	Bit4	Bit5	Bit6	Bit7	Bit8	Bit9	Bit10	Bit11	Bit12	Bit13	Bit14

Conservation of the Register Information

The U3745BM has an integrated power-on reset and brown-out detection circuitry to provide a mechanism to preserve the RAM register information.

According to figure 20, a power-on reset (POR) is generated if the supply voltage V_S drops below the threshold voltage $V_{ThReset}$. The default parameters are programmed into the configuration registers in that condition. Once V_S exceeds $V_{ThReset}$, the POR is canceled after the minimum reset period t_{Rst} . A POR is also generated when the supply voltage of the receiver is turned on.

To indicate that condition, the receiver displays a reset marker (RM) at Pin DATA after a reset. The RM is repre-

sented by the fixed frequency f_{RM} at a 50% duty cycle. RM can be canceled via an 'L' pulse t_1 at Pin DATA. The RM implies the following characteristics:

- f_{RM} is lower than the lowest feasible frequency of a data signal. By this means, RM cannot be misinterpreted by the connected μC .
- If the receiver is set back to polling mode via pin DATA, RM cannot be canceled by accident if t_1 is applied according to the proposal in the section 'Programming the configuration registers'.

By means of that mechanism, the receiver cannot lose its register information without communicating that condition via the reset marker RM.

Figure 20. Generation of the power-on reset

Absolute Maximum Ratings

Parameters	Symbol	Min.	Typ.	Max.	Unit
Supply voltage	V_S			6	V
Power dissipation	P_{tot}			450	mW
Junction temperature	T_j			150	°C
Storage temperature	T_{stg}	-55		+125	°C
Ambient temperature	T_{amb}	-40		+85	°C
Maximum input level, input matched to 50 Ω	P_{in_max}			10	dBm

Thermal Resistance

Parameters	Symbol	Value	Unit
Junction ambient	R_{thJA}	100	K/W

Electrical Characteristics

All parameters refer to GND, $V_S = 5$ V, $T_{amb} = 25^\circ\text{C}$, $f_0 = 433.92$ MHz and $f_0 = 315$ MHz, unless otherwise specified. The possible operating range refer to different circuit conditions: $V_S = 4.5$ V to 5.5 V, $T_{amb} = -40^\circ\text{C}$ to $+85^\circ\text{C}$

Parameters	Test Conditions / Pins	Symbol	Min.	Typ.	Max.	Unit
Current consumption	Sleep mode (XTO and polling logic active)	I_{Soff}		190	350	μA
	IC active (startup-, bitcheck-, receiving mode) Pin DATA = H	I_{Son}		7.0	8.6	mA
LNA mixer						
Third-order intercept point	LNA/ mixer/ IF amplifier input matched according to figure 6	IIP3		-28		dBm
LO spurious emission @ RF_{in}	Input matched according to figure 6, required according to I-ETS 300220	IS_{LORF}		-73	-57	dBm
Noise figure LNA and mixer (DSB)	Input matching according to figure 6	NF		7		dB
LNA_IN input impedance	@ 433.92 MHz @ 315 MHz	Z_{iLNA_IN}		1.0 1.56 1.3 1.0		k Ω pF k Ω pF
1 dB compression point (LNA, mixer, IF amplifier)	Input matched according to figure 6, referred to RF_{in}	IP_{1db}		-40		dBm
Maximum input level	Input matched according to figure 6, BER $\leq 10^{-3}$, ASK mode	P_{in_max}			-23	dBm dBm
Local oscillator						
Operating frequency range VCO		f_{VCO}	309		439	MHz

Parameters	Test Conditions / Pins	Symbol	Min.	Typ.	Max.	Unit
Loop bandwidth of the PLL	For best LO noise (design parameter) R1 = 820 Ω C9 = 4.7 nF C10 = 1 nF	B _{Loop}		100		kHz
Capacitive load at Pin LF	The capacitive load at Pin LF is limited if bitcheck is used. The limitation therefore also applies to self polling.	C _{LF_tot}			10	nF

Electrical Characteristics (continued)

All parameters refer to GND, $V_S = 5\text{ V}$, $T_{\text{amb}} = 25^\circ\text{C}$, $f_0 = 433.92\text{ MHz}$ and $f_0 = 315\text{ MHz}$, unless otherwise specified. The possible operating range refer to different circuit conditions: $V_S = 4.5\text{ V}$ to 5.5 V , $T_{\text{amb}} = -40^\circ\text{C}$ to $+85^\circ\text{C}$

Ozone Depleting Substances Policy Statement

It is the policy of **Atmel Germany GmbH** to

1. Meet all present and future national and international statutory requirements.
2. Regularly and continuously improve the performance of our products, processes, distribution and operating systems with respect to their impact on the health and safety of our employees and the public, as well as their impact on the environment.

It is particular concern to control or eliminate releases of those substances into the atmosphere which are known as ozone depleting substances (ODSs).

The Montreal Protocol (1987) and its London Amendments (1990) intend to severely restrict the use of ODSs and forbid their use within the next ten years. Various national and international initiatives are pressing for an earlier ban on these substances.

Atmel Germany GmbH has been able to use its policy of continuous improvements to eliminate the use of ODSs listed in the following documents.

1. Annex A, B and list of transitional substances of the Montreal Protocol and the London Amendments respectively
2. Class I and II ozone depleting substances in the Clean Air Act Amendments of 1990 by the Environmental Protection Agency (EPA) in the USA
3. Council Decision 88/540/EEC and 91/690/EEC Annex A, B and C (transitional substances) respectively.

Atmel Germany GmbH can certify that our semiconductors are not manufactured with ozone depleting substances and do not contain such substances.

We reserve the right to make changes to improve technical design and may do so without further notice.

Parameters can vary in different applications. All operating parameters must be validated for each customer application by the customer. Should the buyer use Atmel Wireless & Microcontrollers products for any unintended or unauthorized application, the buyer shall indemnify Atmel Wireless & Microcontrollers against all claims, costs, damages, and expenses, arising out of, directly or indirectly, any claim of personal damage, injury or death associated with such unintended or unauthorized use.

Data sheets can also be retrieved from the Internet: <http://www.atmel-wm.com>
