

## SINGLE CHIP 900MHz RF TRANSCEIVER

### Features

- Complete one-chip RF transceiver front end
- Two on-chip local oscillators
- I/Q input interface
- Single power supply 2.7 - 3.3 V
- Low power BiCMOS technology
- On-chip RF power amplifier
- Power selectivity (-2dBm or +14dBm)
- Ambient temperature range (-40°C to +85°C)

### Applications

- 900 MHz Digital Telephones
- Wireless Communication Products
- CT-2 cordless phone
- 902-928 MHz ISM Band Applications

### Description

The BT1074B is a BiCMOS monolithic integrated RF transceiver. With an RF input/output signal range of 850MHz to 950MHz, it is ideally suited for use in digital cordless phones. In addition to the input I/Q interface, the IC contains all of the required components to implement a complete RF-IF transceiver. This includes two on-chip local oscillators, a low noise amplifier with an overall noise figure of less than 3.5dB over temperature and power supply variations, two highly linear down-conversion mixers, an IF amplifier, an up-conversion mixer and an on-chip power amplifier capable of delivering -2dBm to +14dBm. The unit operates with a power supply voltage range of 2.7 - 3.3 volts.

### Specifications

Parameters	Min.	-3σ	Typ.	+3σ	Max.	Units
<b>Overall:</b>						
Power supply	2.7		3.0		3.3	V
Standby current	3		5		7	uA
Frequency operation	850				950	MHz
<b>Receiver:</b>						
Gain (with an optional IF AMP)	18		26		50	dB
Noise Figure			3.5			dBm
Input IP3			-13			dB
Current consumption (w/ RF VCO)			80			mA
<b>Transmitter:</b>						
Gain (with an optional IF AMP)			16			dB

33	IF_VCO_EN	I	IF VCO power down control

---

**Detailed Pin Description:****RECEIVER****RF\_INP and RF\_INN (Pin 4 and Pin 2)****RF Differential Inputs**

RF\_INP and RF\_INN are the differential Inputs of the LNA. An AC coupling capacitor of 10pF is required. RF differential inputs are generated by an external phase-splitter circuit and a matching circuit as shown in the **Application Circuit**. For optimum performance, the component lead length of the external phase-splitter circuit and PCB traces to the LNA input pins should be minimized. Also, the ground plane must surround the phase-splitter circuit to prevent noise coupling from other circuits. The frequency range is from 800MHz to 1000MHz.

**RMX\_OUTP and RMX\_OUTN (Pin 58 and Pin 57)****First IF Differential Outputs**

These are the differential outputs of the internal IF buffers. With the external IF combiner circuit as shown in the **Application Circuit**, the differential outputs become a single-ended output to drive a 150.05MHz BPF SAW filter. These internal IF buffers have open-drain outputs to drive an input impedance of a 700  $\Omega$  BPF through the external combiner circuit.

**MIXERINP (Pin 54)****Second IF Amplifier Input**

The output of a 150.05MHz BPF SAW filter is connected to this pin for the second stage down-conversion. No AC coupling is required.

**MIXOUTP and MIXOUTN (Pin 51 and Pin 52)****Second IF Differential Outputs**

These are the second IF Amp differential outputs. The gain of the IF Amp can be controlled by connecting MIXOUTP through a resistor to ground. A 470  $\Omega$  resistor to ground gives a 0 dB gain. The other Amp output, MIXOUTN, is fed to a 10.7MHz BPF through an AC coupling (0.1uF) capacitor.

**VCO2\_IN (Pin 55)****External Clock Input**

A clock of 139.35MHz is fed to this pin to down-convert the first IF at 150.05MHz to 10.7MHz. No AC coupling is required.

**VDDLNA (Pin 63 and Pin 64)****LNA power**

VDDLNA supplies power to the first and second stage of the LNA. Since the LNA input signal level is small and high frequency, the VDDLNA should be decoupled very close to the chip (for example within 0.25 inches of the package).

**GNDLNA1P, GNDLNA1N and GNDLNA (Pin 5, Pin 1 and Pin 3)****LNA Ground**

GNDLNA1P and GNDLNA1N pins are the ground for the first stage of the LNA and GNDLNA is the ground for the second stage of the LNA. GNDLNA1P and GNDLNA1N are internally separated. For stability and optimum performance, the GNDLNA1P and GNDLNA1N should be physically short.

**VDD\_DMX (Pin 60)****Down Converter Power**

VDD\_DMX supplies power to the down conversion mixers.

**GND\_DMX (Pin 61 and Pin 62)****Down Converter Ground**

GND\_DMX is the ground for the down-conversion mixers. This ground connection is recommended to be shorted via holes to the ground plane below.

**VDD\_IF and VDDR\_X\_BUF (Pin 59 and Pin 50)****IF Buffers and Second Down-Conversion Mixers Power**

Both power supplies require 0.1µF bypass capacitors to ground.

**GND\_IF and GNDR\_X\_BUF (Pin 56 and Pin 53)****IF Buffers and Second Down-Conversion Mixers Ground**

GND\_IF is the ground for the internal IF buffers, and GNDR\_X\_BUF is the ground for the second down-conversion mixers and IF amplifiers.

**TRANSMITTER****RF\_OUTN and RF\_OUTP (Pin 8 and Pin 10)****Power Amplifier Outputs**

These are the differential outputs of the power amplifier which requires a combining network as shown in the **Application Circuit**. The combiner converts the differential signals to a single-ended signal and provides a matching impedance to 50 Ω as well. DC bias to VDD is required since these are open-collector outputs, and AC coupling is needed after the combiner as shown.

**LEXTN and LEXTP (Pin 16 and Pin 17)****Preamplifier Amplifier Outputs**

These are the differential outputs of the preamplifier, which are open-collector types. Two inductors to VDD are required for tuning the preamplifier to the desired frequency band. Recommended values for 900MHz are shown in the **Application Circuit**. Since these are also inputs to the power amplifier, the inductors should be close to the pins and isolated from the power amplifier output to avoid output feedback to these two pins, which may cause instability for the power amplifier.

**REXT1 and REXT2 (Pin 14 and Pin 12)****Preamplifier/Power Amplifier Bias/Gain Adjust**

REXT1 is the biasing resistor for the preamplifier, and REXT2 is the biasing resistor for the power amplifier. For an output power of +14dBm, recommended values are 330 Ω for REXT1 and 4.7 kΩ for REXT2. Increasing REXT1 and lowering REXT2 will lower output power, and vice versa.

**TXQ, M\_REF and TXI (Pin 28, Pin 29 and Pin 30)****Baseband Data Inputs**

These are the inputs which interface with the data signals from the digital signal processor (DSP) or microprocessor (µP). TXI and TXQ are inphase (I) and quadrature (Q) signals, respectively. M\_REF is the DC signal coming from the DSP/µP. All of these pins require a DC level of VDD/2, and a voltage swing of 500mVp-p is required for TXI and TXQ. The **Application Circuit** shows a technique to interface with 1Vp-p I and Q signals with a 6dB voltage attenuator with DC reference to M\_REF pin. A low pass filter may also be required to reject sampling noise from the DSP/µP.

**VDDPA\_GR (Pin 6)****Power Supply for Guard Ring of Power Amplifier**

This power supply pin is only for the output stage of power amplifier. It should be decoupled right at the pin before sharing with other power supplies.

**VDD\_PRE (Pin 19 and Pin 20)*****Power Supply for Preamplifier***

These are the power supply pins dedicated to the preamplifier. Decoupling should be done right at these pins to a ground plane, if possible.

**VDD\_UPC (Pin 21)*****Power Supply for RF Up-Conversion Mixers***

This is a dedicated power supply pin for the RF up-conversion mixers. Decoupling should be done right at this pin to a ground plane, if possible.

**VDD\_TXIF (Pin 31)*****Power Supply for Input Buffers and IF Up-Conversion Mixers***

The input buffers and IF up-conversion mixers share this power supply on-chip. Besides the usual high frequency decoupling, it should be decoupled for low frequency, up to 10MHz.

**GND\_PA (Pin 7, Pin 9 and Pin 11) - Ground Pins for the Power Amplifier**

**GND\_PRE (Pin 13, Pin 15 and Pin 18) - Ground Pins for the Preamplifier**

**GND\_UPC (Pin 22 and Pin 23) - Ground Pins for the RF Up-Conversion Mixers**

**GND\_TXIF (Pin 27) - Ground Pin for the Input Buffers and IF Up-Conversion Mixers**

These are the dedicated ground pins which can share the same ground as long as a good ground plane is available.

**RFVCO****RF\_VCO\_CTRL (Pin 45)*****RFVCO Input Control***

An external tank circuit is connected to the RFVCO Input Control pin (see Application Circuit). The tank circuit generates the overall oscillation frequency for the RFVCO and therefore must be optimized to avoid any interference from other components. The RF\_VCO\_CTRL pin and the external PLL completes the RF-PLL loop that generates a fixed oscillation frequency for the RFVCO.

**RF\_VCO\_OUT (Pin 43)*****RF\_VCO Output***

The RF\_VCO\_OUT pin is connected to the external PLL to complete the RF-PLL loop. The PLL applies a DC voltage to the input tank circuit based on the detected RF\_VCO\_OUT signal. This DC voltage produces the negative bias voltage required by the Varactor to generate the necessary capacitance for the tank circuit network.

**VDDRFVCOIN and GNDRFVCOIN (Pin 47 and Pins 44)*****RFVCO Input Stage Power Supply and Ground***

VDDRFVCOIN is the power supply for the input stage of the RFVCO. For optimum performance, VDDRFVCOIN should be bypassed to GNDRFVCOIN using a low-inductance/high frequency coupling capacitor. The input stage of the RFVCO is very critical in generating the overall frequency of the RFVCO; therefore isolating these power supply pins will enhance the overall performance of the RFVCO.

**VDDRF\_VCO and GNDRF\_VCO (Pin 41 and Pin 42)*****RFVCO Power Supply and Ground***

VDDRF\_VCO and GNDRF\_VCO provide the power supply source for the other stages of the RFVCO.

**RFVCOCAPIN (Pin 46)*****RFVCO Feedback Capacitors input***

This pin provides an off-chip capacitive feedback loop to the RF VCO.

## IF VCO

### IF\_VCO\_CTRL (Pin 35)

#### **IF VCO Input**

This pin is connected to the external tank circuit as the VCO input. Its frequency is tuned to 600MHz.

### IF\_VCO\_OUTP and IF\_VCO\_OUTN (Pin 38 and Pin 37 )

#### **IF VCO Differential Outputs**

These differential outputs are an open-collector type that needs to be connected to an external power supply through 50Ω resistors. The VCO's oscillation frequency can be controlled by connecting *either one* of its differential outputs to a PLL as shown in the **Application Circuit**.

### VDD\_IFVCOIN (Pin 32)

#### **VCO Input Power Supply**

The IF VCO has two power supplies, VDD\_IFVCOIN (Pin 32) and VDDIF\_VCO (Pin 40). VDD\_IFVCOIN is the first stage VCO power. A large capacitor of at least 100pF is recommended to be connected between this pin and ground for filtering out noise.

### VDDIF\_VCO (Pin 40)

#### **VCO Buffer Power Supply**

This pin provides power to the internal VCO buffer circuitry.

### GND\_IFVCOIN (Pin 34)

#### **VCO Input Ground**

This pin is the first stage VCO ground.

### GNDIF\_VCO (Pin 39)

#### **VCO Ground**

This pin is ground for the internal VCO circuitry.

### IFCAPIN (Pin 36)

#### **VCO Feedback Capacitors Input**

This pin provides an off-chip capacitive feedback loop to the VCO oscillator.

## POWER SAVING/POWER DOWN PINS

The following pins are all CMOS digital interface.

### TX\_P\_CNT (Pin 24)

#### **Transmission Output Power Control**

This pin controls the power amplifier output with two levels. A HIGH signal puts the power amplifier in low power mode with -2dBm output power. A LOW signal puts the power amplifier in high power mode with +14dBm output power. These power levels are based upon the resistor value shown for REXT1 & REXT2.

### PA\_EN (Pin 25)

#### **Transmitter Power Amplifier Power Down Control**

This is the power down control pin for the power amplifier and preamplifier, separate from the transmitter power down. A HIGH signal turns the amplifiers on while a LOW signal turns them off.

### TX\_EN (Pin 26)

#### **Transmitter Power Down Control**

This pin controls the power down function of the entire transmitter, excluding the power amplifier and preamplifier. A HIGH signal turns the circuit on while a LOW signal turns the circuit off.

## IF\_VCO\_EN (Pin 33)

### IF VCO Power Down Control

This pin controls the power down function of the IF VCO, which is used by the transmitter section during transmission. A HIGH signal turns the circuit off while a LOW signal turns the circuit on.

## RF\_VCO\_EN (Pin 48)

### RF VCO Power Down Control

This pin controls the power-down function of the RF VCO, which is used by the transmitter and the receiver. A HIGH signal turns the circuit off while a LOW signal turns the circuit on.

## RX\_EN (Pin 49)

### Receiver Power Down Control

This pin controls the power down function of the entire receiver. A HIGH signal turns the circuit on while a LOW signal turns the circuit off.

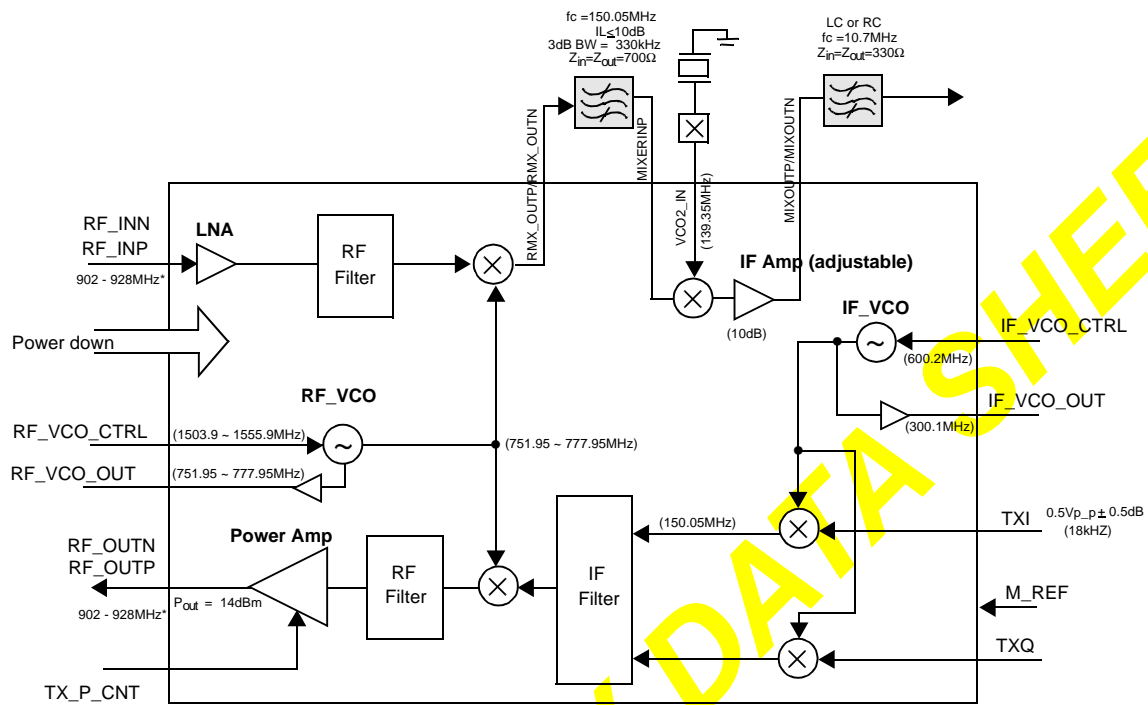

The recommended TDD mode as well as power saving mode usage of all of these control pins are as follows:

Pins	Communication Mode		Power Save Mode*
	TX	RX	
TX_EN	HI	LO	LO
PA_EN	HI	LO	LO
RX_EN	LO	HI	LO
RF_VCO_EN	LO	LO	HI
IF_VCO_EN	LO	LO	HI
TX_P_CNT	LO	LO	HI

## APPLICATION INFORMATION:

The BT1074B is a complete RF transceiver which integrates the receiver, transmitter and local oscillator functions into one chip. Designed to operate in TDD mode, the chip supports CT-2 and digital cordless phone and ISM band applications.

The transmitter accepts I&Q inputs from the system interface which also provides the DC reference level to M\_REF pin. An on-chip RF filter removes spurious signals before going to the on-chip power amplifier. RF outputs are differential and a power combining network is required for converting to a single-ended interface with an output load (see **Application Circuit**). A power control pin selects between high or low transmission power mode, which ranges from +14dBm to -2dBm. Power level can also be set with resistors at REXT2 and REXT1 pins.

In the receiver section an on-chip bandpass filter is provided between the LNA output and downconverter mixer input for optimum noise performance. The first IF outputs at 150.05MHz are differential and require a power combiner. The second IF mixer downconverts the first IF signal from 150.05MHz to 10.7MHz by an external crystal clock input at 139.35MHz. A gain-adjustable IF amplifier provides additional gain up to 10dB.

The RF local oscillator and the transmitter IF oscillator are conveniently provided on-chip and can be used with an external dual PLL frequency synthesizer. Both of the RF and IF local oscillators require external tuning elements, as shown in the **Application Circuit**.

Each of the receiver, transmitter, and the two oscillators can be put into sleep mode with on-chip power-down control pins. These functions can be turned on or off by a microcontroller. For example, in the receiving mode, the microcontroller will turn on the receiver and RF and IF VCOs and will turn off the transmit function. In the transmitting mode, the microcontroller will turn on the transmitter, RF and IF VCOs, and will turn off the receiver function. If needed, the PA\_EN pin can be used to slowly ramp up or down the power amplifier output level by applying an externally generated linear voltage ramp.

The recommended usage of BT1074B in a CT2 system application is shown in Figure 1:
