Description

The Edge622 and Edge624 are dual and quad (respectively) delay and deskew elements. Manufactured in a high performance bipolar process, they are designed primarily for channel deskew applications in Memory Test Equipment.

The parts offer three distinct full scale delay ranges of 14 ns, 24 ns, and 34 ns. In the 14 ns and 24 ns ranges, independent adjustment of the rising edge vs. the falling edge is achievable.

The Edge622 and Edge624 have a drive mode, where one input signal is routed to all of the outputs. This mode is particularly useful in a fanout application.

The delay value (and resolution) is controlled via an external voltage DAC.

These deskew elements are designed specifically to be monotonic and stable while delaying a very narrow pulse over a wide delay range.

Features

- Pin and Functionally Compatible with the Bt622 and Bt624
- Independent Delay Adjustments for Positive and Negative Transitions
- Fanout Mode for One Input Distributed to All Channels
- 28-pin or 44-pin Plastic J-Lead (PLCC) Package with Internal Heat Spreader

Applications

- Automatic Test Equipment
 - Memory Tester Drive Only Channel Deskew
 - I/O Channel Deskew

Chip Overview

The Edge624 is a quad, and the Edge622 is a dual, delay line and deskew element. Each part offers three ranges of delay (Tspan); 14 ns, 24 ns, or 34 ns, where the VDELAY inputs adjust the overall propagation delay of the part. In addition, the parts support a separate rising and falling edge delay for the 14 ns and 24 ns ranges only, where the VWIDTH inputs control the falling edge delay. There is also a drive mode, where the channel 2 input drives all four Edge624 outputs (or channel 1 drives both Edge622 outputs), with all other inputs ignored.

The Edge622 and Edge624 are designed to be monotonic and very stable in all modes of operation.

Figures 1 and 2 show simplified block diagrams of the two parts.

Data Sheet Nomenclature

The remainder of the data sheet will be written for the Edge624. All circuit descriptions also pertain to the Edge622, only channels 3 and 4 will not apply.

Operating Modes

The Edge624 has 5 modes of operation, which are described in Table 1. (Mode 4 is not a valid mode.)

Mode	S1	S0	TSPAN	VWIDTH
0	0	0	14 ns	N/A
1	0	1	24 ns	N/A
2	1	0	14 ns	±5 ns
3	1	1	24 ns	±5 ns
4	VEE	0	N/A	N/A
5	VEE	1	34 ns	N/A

Table 1. Delay Ranges Versus Mode

Modes 0, 1, and 5

Modes 0, 1, and 5 are simple delay modes (see Figures 3 and 4). An input signal comes into each channel and is delayed by some programmable amount determined by the analog input VDELAY.

The rising and falling edges are delayed equally. The VWIDTH analog input has no function in modes 0 and 2, and VWIDTH must be connected to VDELAY in mode 5. The propagation delay for a rising and falling edge is defined as

$$T_{pd+}, T_{pd-} = T_{pd(min)} + T_{span}$$

where $T_{pd(min)}$ is the raw propagation delay of the part with minimum programmed delay, and T_{span} is the additional delay programmed via the VDELAY input.

Figure 4. Modes 0, 1, and 5 Functional Diagram

Edge624 Tspan vs. VDELAY

Figure 5. Tspan Transfer Function

Analog Delay Inputs

VDELAY and VWIDTH are analog voltage inputs which control the delay of the rising and falling edge. VDELAY and VWIDTH vary from -0.1V (minimum delay) to -1.3V (maximum delay).

These inputs are designed to sink a constant input current, typically 1.0 mA (with $R_{EXT1} = 1.3 \text{ K}\Omega$), over their operating range from -0.1V to -1.3V. Any voltage DAC used to drive these inputs directly needs to source 1.0 mA. Any current DAC used needs to factor in the constant 1.0 mA input current.

The equation used to establish the VDELAY and VWIDTH input currents is:

$$I(VWIDTH, VDELAY) = 1.3V / R_{EXT1}.$$

The transfer function for Tspan vs. VDELAY is shown for all modes in Figure 5.

Modes 2 and 3

Modes 2 and 3 allow independent adjustment of the rising and falling edges (see Figures 6 and 7). The propagation delay for a rising edge is defined as

$$T_{pd+} = T_{pd(min)} + T_{span}$$

where $T_{pd(min)}$ is the raw propagation delay of the part with minimum programmed delay, and T_{span} is the additional delay programmed via the VDELAY input.

The propagation delay for a falling edge is defined as

$$T_{pd-} = T_{pd(min)} + T_{span} + T_{width}$$

where T_{width} is defined as the additional delay incurred by adjusting the VWIDTH input. Notice that T_{width} can be either positive or negative over a ± 5 ns range. This flexibility allows the part to either expand or contract an input signal (see Figure 6).

Notice also that T_{pd+} is a function of VDELAY only, while T_{pd-} is a function of VDELAY and VWIDTH. The transfer function for T_{span} vs. VDELAY is shown for both modes in figure 5. The transfer function for T_{width} vs. VWIDTH and VDELAY is shown in Figure 8.

Programming Sequence

VDELAY, in addition to affecting the placement of the rising edge, also affects the falling edge. Therefore, when calibrating a system, VDELAY should be adjusted first. As VWIDTH affects only the falling edge, it should be adjusted after VDELAY is established.

Drive Mode

With $DRVMODE = 1$, the input signal on channel 2 will be routed to all Edge624 delay paths. (Channel 1 will be routed to both Edge622 outputs.) In drive mode, all 5 operating modes still offer the same delay range and edge control features. The only difference is that the input signal now comes from channel 2, while all other inputs (IN/IN^*) are ignored.

Figures 9 through 12 show a simplified model for drive mode.

Figure 11. Edge622 Drive Mode for Operating Modes 2 and 3.

Figure 12. Edge624 Drive Mode for Operating Modes 2 and 3.

Power Up Initialization

Note: Modes 2 and 3 use an SR flip-flop at the output stage; modes 0, 1, and 5 do not. Therefore, upon power up in modes 2 or 3, or when operating modes are being changed into modes 2 or 3, the SR flip-flop is in an indeterminate state and the output may not reflect the input condition. A rising or falling edge that propagates through the channel will correctly reset the part. Therefore, in mode 2 or 3, a dummy edge should be applied before calibration or real time execution.

Notice also that in modes 0, 1, and 5 there is no flip-flop. The output will therefore always reflect the status of the inputs.

Minimum Pulse Width

The minimum pulse width that the part can support is a function of the operating mode and the programmed delay value. Figures 13, 14, and 15 document the maximum usable delay for all modes and ranges.

Linearity

The Edge622 and Edge624 are designed to be monotonic and stable, although not necessarily linear. However, there is a characteristic nonlinearity curve associated with each operating mode of the part. Figures 16, 17, and 18 show this nonlinearity.
