

HT46R22 8-Bit A/D Type OTP MCU

Features

- Operating voltage: f_{SYS}=4MHz: 3.3V~5.5V f_{SYS}=8MHz: 4.5V~5.5V
- 19 bidirectional I/O lines (max.)
- 1 interrupt input shared with an I/O line
- 8-bit programmable timer/event counter with overflow interrupt and 7-stage prescaler
- On-chip crystal and RC oscillator
- Watchdog Timer
- 2048×14 program memory PROM
- 64×8 data memory RAM
- Supports PFD for sound generation
- HALT function and wake-up feature reduce power consumption
- + Up to $0.5\mu s$ instruction cycle with 8MHz system clock at $V_{DD}{=}5V$

General Description

The device is an 8-bit high performance RISC-like microcontroller designed for multiple I/O product applications. It is particularly suitable for use in products such as washing machine controllers and home appliances. A HALT feature is included to reduce power consumption.

- 6-level subroutine nesting
- 8 channels 9-bit resolution (8-bit accuracy) A/D converter
- 1-channel (6+2)/(7+1)-bit PWM output shared with two I/O lines
- Bit manipulation instruction
- 14-bit table read instruction
- 63 powerful instructions
- All instructions in one or two machine cycles
- Low voltage reset function
- I²C BUS (slave mode)
- 24-pin SKDIP/SOP packages

The program and option memories can be electrically programmed, making this microcontroller suitable for product development applications.

I²C is a trademark of Philips Semiconductors.

Pin Description

Pin No.	Pin Name	I/O	ROM Code Option	Description
10 9 8 7 2 1 24 23	PB0/AN0 PB1/AN1 PB2/AN2 PB3/AN3 PB4/AN4 PB5/AN5 PB6/AN6 PB7/AN7	I/O	Pull-high	Bidirectional 8-bit input/output port. Software instructions deter- mine the CMOS output, Schmitt trigger input with or without pull-high resistor (determined by pull-high option: port option) or A/D input. Once a PB line is selected as an A/D input (by using software control), the I/O function and pull-high resistor are disabled auto- matically.
6~4 3 22 21 20 19	PA0~PA2 PA3/PFD PA4/TMR PA5/INT PA6/SDA PA7/SCL	I/O	Pull-high Wake-up PA3 or PFD I/O or Serial Bus	Bidirectional 8-bit input/output port. Each bit can be configured as wake-up input by ROM code option. Software instructions determine the CMOS output or Schmitt trigger input with or without pull-high resistor (determined by pull-high options: bit option). The PFD, TMR and \overline{INT} are pin-shared with PA3, PA4 and PA5, respectively. Once the I ² C BUS function is used, the internal registers related to PA6 and PA7 can not be used.
11	VSS			Negative power supply, ground.
12~13	PC0~PC1	I/O	Pull-high	Bidirectional 2-bit input/output port. Software instructions deter- mine the CMOS output, Schmitt trigger input with or without pull-high resistor (determine by pull-high option: port option).
14	PD0/PWM	I/O	Pull-high I/O or PWM	Bidirectional 1-bit input/output port. Software instructions deter- mine the CMOS output, Schmitt trigger input with or without a pull-high resistor (determined by pull-high option: port option). The PWM output function is pin-shared with PD0 (dependent on PWM optios).
15	RES	I		Schmitt trigger reset input. Active low.
16	VDD	_		Positive power supply
17 18	OSC1 OSC2	 0	Crystal or RC	OSC1, OSC2 are connected to an RC network or a Crystal (de- termined by ROM code option) for the internal system clock. In the case of RC operation, OSC2 is the output terminal for 1/4 sys- tem clock.

Absolute Maximum Ratings

Supply Voltage	V _{SS} –0.3V to V _{SS} +5.5V	Storage Temperature	.–50°C to 125°C
Input Voltage	.V _{SS} =0.3V to V _{DD} +0.3V	Operating Temperature	40°C to 85°C

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

Functional Description

Execution flow

The system clock for the microcontroller is derived from either a crystal or an RC oscillator. The system clock is internally divided into four non-overlapping clocks. One instruction cycle consists of four system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch takes an instruction cycle while decoding and execution takes the next instruction cycle. However, the pipelining scheme causes each instruction to effectively execute in a cycle. If an instruction changes the program counter, two cycles are required to complete the instruction.

Program counter – PC

The program counter (PC) controls the sequence in which the instructions stored in program PROM are executed and its contents specify full range of program memory.

After accessing a program memory word to fetch an instruction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code. When executing a jump instruction, conditional skip execution, loading PCL register, subroutine call, initial reset, internal interrupt, external interrupt or return from subroutine, the PC manipulates the program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instructions. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed with the next instruction.

The lower byte of the program counter (PCL) is a readable and writeable register (06H). Moving data into the PCL performs a short jump. The destination will be within 256 locations.

When a control transfer takes place, an additional dummy cycle is required.

Program memory – PROM

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized into 2048×14 bits, addressed by the program counter and table pointer.

cation 000H.

Location 004H

This area is reserved for the external interrupt service program. If the $\overline{\text{INT}}$ input pin is activated, the interrupt is enabled and the stack is not full, the program begins execution at location 004H.

Location 008H

Program Memory This area is reserved for the timer/event counter interrupt service program. If a timer interrupt results from a timer/event counter overflow, and if the interrupt is enabled and the stack is not full, the program begins execution at location 008H.

• Location 00CH

This area is reserved for the A/D converter interrupt service program. If an A/D converter interrupt results from an end of A/D conversion, and if the interrupt is enabled and the stack is not full, the program begins execution at location 00CH.

Location 010H

This area is reserved for the l^2C BUS interrupt service program. If the l^2C BUS interrupt resulting from a slave address is match or completed one byte of data transfer, and if the interrupt is enable and the stack is not full, the program begins execution at location 010H.

Table location

Any location in the PROM space can be used as look-up tables. The instructions "TABRDC [m]" (the

current page, 1 page=256 words) and "TABRDL [m]" (the last page) transfer the contents of the lower-order byte to the specified data memory, and the higher-order byte to TBLH (08H). Only the destination of the lower-order byte in the table is well-defined, the other bits of the table word are transferred to the lower portion of TBLH, and the remaining 2 bit is read as "0". The Table Higher-order byte register (TBLH) is read only. The table pointer (TBLP) is a read/write register (07H), which indicates the table location. Before accessing the table, the location must be placed in TBLP. The TBLH is read only and cannot be restored. If the main routine and the ISR (Interrupt Service Routine) both employ the table read instruction, the contents of the TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors can occur. In other words, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both the main routine and the ISR, the interrupt is supposed to be disabled prior to the table read instruction. It will not be enabled until the TBLH has been backed up. All table related instructions require two cycles to complete the operation. These areas may function as normal program memory depending upon the requirements.

Stack register – STACK

This is a special part of the memory which is used to save the contents of the program counter (PC) only. The stack is organized into 6 levels and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the stack pointer (SP) and is neither readable nor writeable. At a subroutine call or interrupt acknowledgment, the contents of the program counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the SP will point to the top of the stack.

If the stack is full and a non-masked interrupt takes place, the interrupt request flag will be recorded but the acknowledgment will be inhibited. When the stack pointer is decremented (by RET or RETI), the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. In a similar case, if the stack is full and a "CALL" is subsequently executed, stack overflow occurs and the first entry will be lost (only the most recent 6 return addresses are stored).

Data memory - RAM

The data memory is designed with 92×8 bits. The data memory is divided into two functional groups: special function registers and general purpose data memory (64×8). Most are read/write, but some are read only.

RAM mapping

The special function registers include the indirect addressing register (00H), timer/event counter register (TMR;0DH), timer/event counter control register (TMRC;0EH), program counter lower-order byte register (PCL;06H), memory pointer register (MP;01H), accumulator (ACC;05H), table pointer (TBLP;07H), table higher-order byte register (TBLH;08H), status register (STATUS;0AH), interrupt control register 0 (INTC0;

0BH), PWM data register (PWM;1AH), the I²C BUS slave address register (HADR;20H), the I²C BUS control register (HCR;21H), the I²C BUS status register (HSR;22H), the I²C BUS data register (ADR;23H), the A/D result lower-order byte register (ADRL;24H), the A/D result higher-order byte register (ADRH;25H), the A/D control register (ADCR;26H), the A/D control register (ADCR;26H), the A/D control register (ACSR;27H), I/O registers (PA;12H, PB;14H, PC;16H, PD;18H) and I/O control registers (PAC;13H, PBC;15H, PCC;17H, PDC;19H). The remaining space before the 40H is reserved for future expanded usage and reading these locations will get "00H". The general purpose data memory, addressed from 40H to 7FH, is used for data and control information under instruction commands.

All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by "SET [m].i" and "CLR [m].i". They are also indirectly accessible through memory pointer register (MP;01H).

Indirect addressing register

Location 00H is an indirect addressing register that is not physically implemented. Any read/write operation of [00H] accesses data memory pointed to by MP (01H). Reading location 00H itself indirectly will return the result 00H. Writing indirectly results in no operation.

The memory pointer register MP (01H) is a 7-bit register. The bit 7 of MP is undefined and reading will return the result "1". Any writing operation to MP will only transfer the lower 7-bit data to MP.

Accumulator

The accumulator is closely related to ALU operations. It is also mapped to location 05H of the data memory and can carry out immediate data operations. The data movement between two data memory locations must pass through the accumulator.

Arithmetic and logic unit - ALU

This circuit performs 8-bit arithmetic and logic operations. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ)

The ALU not only saves the results of a data operation but also changes the status register.

Status register – STATUS

This 8-bit register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PD), and watchdog time-out flag (TO). It also records the status information and controls the operation sequence.

With the exception of the TO and PD flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PD flag. In addition operations related to the status register may give different results from those intended. The TO flag can be affected only by system power-up, a WDT time-out or executing the "CLR WDT" or "HALT" instruction. The PD flag can be affected only by executing the "HALT" or "CLR WDT" instruction or a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

In addition, on entering the interrupt sequence or executing the subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status are important and if the subroutine can corrupt the status register, precautions must be taken to save it properly.

Labels	Bits	Function
с	0	C is set if the operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
AC	1	AC is set if the operation results in a carry out of the low nibbles in addition or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
Z	2	Z is set if the result of an arithmetic or logic operation is zero; otherwise Z is cleared.
ov	3	OV is set if the operation results in a carry into the highest-order bit but not a carry out of the highest-order bit, or vice versa; otherwise OV is cleared.
PD	4	PD is cleared by system power-up or executing the "CLR WDT" instruction. PD is set by exe- cuting the "HALT" instruction.
то	5	TO is cleared by system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.
_	6, 7	Unused bit, read as "0"

Status register

Interrupt

The device provides an external interrupt, an internal timer/event counter interrupt, the A/D converter interrupt and the I^2C BUS interrupts. The interrupt control register 0 (INTC0;0BH) and interrupt control register 1 (INTC1;1EH) contains the interrupt control bits to set the enable/disable and the interrupt request flags.

Once an interrupt subroutine is serviced, all the other interrupts will be blocked (by clearing the EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may happen during this interval but only the interrupt request flag is recorded. If a certain interrupt requires servicing within the service routine, the EMI bit and the corresponding bit of INTC0 and INTC1 may be set to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decremented. If immediate service is desired, the stack must be prevented from becoming full.

All these kinds of interrupts have a wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack, followed by a branch to a subroutine at specified location in the program memory. Only the program counter is pushed onto the stack. If the contents of the register or status register (STATUS) are altered by the interrupt service program which corrupts the desired control sequence, the contents should be saved in advance.

External interrupts are triggered by a high to low transition of $\overline{\text{INT}}$ and the related interrupt request flag (EIF; bit 4 of INTCO) will be set. When the interrupt is enabled, the stack is not full and the external interrupt is active, a subroutine call to location 04H will occur. The interrupt request flag (EIF) and EMI bits will be cleared to disable other interrupts.

The internal timer/event counter interrupt is initialized by setting the timer/event counter interrupt request flag (TF; bit 5 of INTC0), caused by a timer overflow. When the interrupt is enabled, the stack is not full and the TF bit is set, a subroutine call to location 08H will occur. The related interrupt request flag (TF) will be reset and the EMI bit cleared to disable further interrupts.

The A/D converter interrupt is initialized by setting the A/D converter request flag (ADF; bit 6 of INTC0), caused by an end of A/D conversion. When the interrupt is enabled, the stack is not full and the ADF is set, a subroutine call to location 0CH will occur. The related interrupt request flag (ADF) will be reset and the EMI bit cleared to disable further interrupts.

Register	Bit No.	Label	Function
	0	EMI	Controls the master (global) interrupt (1= enabled; 0= disabled)
	1	EEI	Controls the external interrupt (1= enabled; 0= disabled)
INTC0 (0BH)	2	ETI	Controls the timer/event counter interrupt (1= enabled; 0= disabled)
	3	EADI	Controls the A/D converter interrupt (1= enabled; 0= disabled)
	4	EIF	External interrupt request flag (1= active; 0= inactive)
	5	TF	Internal timer/event counter request flag (1= active; 0= inactive)
	6	ADF	A/D converter request flag (1= active; 0= inactive)
	7		Unused bit, read as "0"

INTC0 register

The I^2C BUS interrupt is initialized by setting the I^2C BUS interrupt request flag (HIF; bit 4 of INTC1), caused by a slave address match (HAAS="1") or one byte of data transfer is completed. When the interrupt is enabled, the stack is not full and the HIF bit is set, a subroutine call to location 10H will occur. The related interrupt request flag (HIF) will be reset and the EMI bit cleared to disable further interrupts.

During the execution of an interrupt subroutine, other interrupt acknowledgments are held until the "RETI" instruction is executed or the EMI bit and the related interrupt control bit are set to 1 (of course, if the stack is not full). To return from the interrupt subroutine, "RET" or "RETI" may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not.

Interrupts, occurring in the interval between the rising edges of two consecutive T2 pulses, will be serviced on the latter of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests the following table shows the priority that is applied. These can be masked by resetting the EMI bit.

No.	Interrupt Source	Priority	Vector
а	External Interrupt	1	04H
b	Timer/event counter Overflow	2	08H
с	A/D Converter Interrupt	3	0CH
d	I ² C BUS Interrupt	4	10H

The timer/event counter interrupt request flag (TF), external interrupt request flag (EIF), A/D converter request flag (ADF), the I²C BUS interrupt request flag (HIF), enable timer/event counter bit (ETI), enable external interrupt bit (EEI), enable A/D converter interrupt bit (EADI), enable I²C BUS interrupt bit (EHI) and enable master interrupt bit (EMI) constitute an interrupt control register 0 (INTC0) and an interrupt control register 1 (INTC1) which are located at 0BH and 1EH in the data memory. EMI, EEI, ETI, EADI, EHI are used to control the enabling/disabling of interrupts. These bits prevent the requested interrupt from being serviced. Once the interrupt request flags (TF, EIF, ADF, HIF) are set, they will remain in the INTC0 and INTC1 register until the interrupts are serviced or cleared by a software instruction.

Register	Bit No.	Label	Function
	0	EHI	Controls the I ² C BUS interrupt (1= enabled; 0= disabled)
	1		Unused bit, read as "0"
	2	_	Unused bit, read as "0"
INTC1	3		Unused bit, read as "0"
(1EH)	(1EH) 4 5	HIF	I ² C BUS interrupt request flag (1= active; 0= inactive)
			Unused bit, read as "0"
	6		Unused bit, read as "0"
	7		Unused bit, read as "0"

INTC1 register

It is recommended that a program does not use the "CALL subroutine" within the interrupt subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications. If only one stack is left and enabling the interrupt is not well controlled, the original control sequence will be damaged once the "CALL" operates in the interrupt subroutine.

Oscillator configuration

There are two oscillator circuits in the microcontroller.

System oscillator

Both are designed for system clocks, namely the RC oscillator and the Crystal oscillator, which are determined by the ROM code option. No matter what oscillator type is selected, the signal provides the system clock. The HALT mode stops the system oscillator and ignores an external signal to conserve power.

If an RC oscillator is used, an external resistor between OSC1 and VSS is required and the resistance must range from $30k\Omega$ to $750k\Omega$. The system clock, divided by 4, is available on OSC2, which can be used to synchronize external logic. The RC oscillator provides the most cost effective solution. However, the frequency of oscillation may vary with VDD, temperatures and the chip itself due to process variations. It is, therefore, not suitable for timing sensitive operations where an accurate oscillator frequency is desired.

If the Crystal oscillator is used, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift required for the oscillator, and no other external components are required. Instead of a crystal, a resonator can also be connected between OSC1 and OSC2 to get a frequency reference, but two external capacitors in OSC1 and OSC2 are required (If the oscillating frequency is less than 1MHz).

The WDT oscillator is a free running on-chip RC oscillator, and no external components are required. Even if the system enters the power down mode, the system clock is stopped, but the WDT oscillator still works with a period of approximately 72μ s/5V. The WDT oscillator can be disabled by ROM code option to conserve power.

Watchdog Timer - WDT

The clock source of the WDT is implemented by an dedicated RC oscillator (WDT oscillator) or instruction clock (system clock divided by 4) decided by ROM code options. This timer is designed to prevent a software malfunction or sequence jumping to an unknown location with unpredictable results. The watchdog timer can be disabled by a ROM code option. If the watchdog timer is disabled, all the executions related to the WDT result in no operation.

Once an internal WDT oscillator (RC oscillator with period 72µs normally) is selected, it is divided by 2^{12} ~ 2^{15} (by ROM code option to get the WDT time-out period). The minimum period of WDT time-out period is about 300ms~600ms. This time-out period may vary with temperature, VDD and process variations. By selection the WDT ROM code option, longer time-out periods can be realized. If the WDT time-out is selected 2^{15} , the maximum time-out period is divided by 2^{15} ~ 2^{16} about 2.3s~4.7s.

If the WDT oscillator is disabled, the WDT clock may still cone from the instruction clock and operate in the same manner except that in the halt state the WDT may stop counting and lose its protecting purpose. In this situation the logic can only be restarted by external logic. If the device operates in a noisy environment, using the on-chip RC oscillator (WDT OSC) is strongly recommended, since the HALT will stop the system clock.

Watchdog Timer

The WDT overflow under normal operation will initialize "chip reset" and set the status bit TO. Whereas in the HALT mode, the overflow will initialize a "warm reset" only the PC and SP are reset to zero. To clear the contents of WDT, three methods are adopted; external reset (a low level to RES), software instructions, or a HALT instruction. The software instructions include CLR WDT and the other set - CLR WDT1 and CLR WDT2. Of these two types of instruction, only one can be active depending on the ROM code option - "CLR WDT times selection option". If the "CLR WDT" is selected (i.e. CLRWDT times equal one). any execution of the CLR WDT instruction will clear the WDT. In case "CLR WDT1" and "CLR WDT2" are chosen (i.e. CLRWDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip because of time-out.

If the WDT time-out period is selected $f_s/2^{12}$ (ROM code option), the WDT time-out period ranges from $f_s/2^{12} \sim f_s/2^{13}$, since the "CLR WDT" or "CLR WDT1" and "CLR WDT2" instructions only clear the last two stages of the WDT.

Power down operation - HALT

The HALT mode is initialized by the "HALT" instruction and results in the following...

- The system oscillator will be turned off but the WDT oscillator keeps running (if the WDT oscillator is selected).
- The contents of the on chip RAM and registers remain unchanged.
- WDT will be cleared and recounted again (if the WDT clock is from the WDT oscillator).
- All of the I/O ports maintain their original status.
- The PD flag is set and the TO flag is cleared.

The system can leave the HALT mode by means of an external reset, an interrupt, an external falling edge signal on port A or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". After the TO and PD flags are examined, the reason for chip reset can be determined.

The PD flag is cleared by system power-up or executing the "CLR WDT" instruction and is set when executing the "HALT" instruction. The TO flag is set if the WDT time-out occurs, and causes a wake-up that only resets the PC and SP; the others keep their original status.

The port A wake-up and interrupt methods can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake up the device by the ROM code option. Awakening from an I/O port stimulus, the program will resume execution of the next instruction. If it is awakening from an interrupt, two sequences may happen. If the related interrupt is disabled or the interrupt is enabled but the stack is full, the program will resume execution at the next instruction. If the interrupt is enabled and the stack is not full, the regular interrupt response takes place. If an interrupt request flag is set to "1" before entering the HALT mode, the wake-up function of the related interrupt will be disabled. Once a wake-up event occurs, it takes 1024 t_{SYS} (system clock period) to resume normal operation. In other words, a dummy period will be inserted after wake-up. If the wake-up results from an interrupt acknowledgment, the actual interrupt subroutine execution will be delayed by one or more cycles. If the wake-up results in the next instruction execution, this will be executed immediately after the dummy period is finished.

To minimize power consumption, all the I/O pins should be carefully managed before entering the HALT status.

Reset

There are three ways in which a reset can occur:

- RES reset during normal operation
- RES reset during HALT
- · WDT time-out reset during normal operation

The WDT time-out during HALT is different from other chip reset conditions, since it can perform a "warm reset" that resets only the PC and SP, leaving the other circuits in their original state. Some registers remain unchanged during other reset conditions. Most registers are reset to the "initial condition" when the reset condi-

tions are met. By examining the PD and TO flags, the program can distinguish between different "chip resets".

то	PD	RESET Conditions	
0	0	RES reset during power-up	
u	u	RES reset during normal operation	
0	1	RES wake-up HALT	
1	u	WDT time-out during normal operation	
1	1	WDT wake-up HALT	

Note: "u" means "unchanged"

To guarantee that the system oscillator is started and stabilized, the SST (System Start-up Timer) provides an extra-delay of 1024 system clock pulses when the system reset (power-up, WDT time-out or $\overline{\text{RES}}$ reset) or the system awakes from the HALT state.

When a system reset occurs, the SST delay is added during the reset period. Any wake-up from HALT will enable the SST delay. The functional unit chip reset status are shown below.

PC	000H
Interrupt	Disable
WDT	Clear. After master reset, WDT begins counting
Timer/event counter	Off

Timer/event counter

A timer/event counter (TMR) is implemented in the microcontroller. The timer/event counter contains an 8-bit programmable count-up counter and the clock may come from an external source or the system clock.

Using the internal system clock, there is only one reference time-base. The internal clock source comes from f_{SYS} . Using external clock input allows the user to count external events, measure time internals or pulse widths, or generate an accurate time base. While using the internal clock allows the user to generate an accurate time base.

There are 2 registers related to the timer/event counter; TMR ([0DH]), TMRC ([0EH]). Two physical registers are mapped to TMR location; writing TMR makes the starting value be placed in the timer/event counter preload register and reading TMR gets the contents of the timer/event counter. The TMRC is a timer/event counter control register, which defines some options.

The TM0, TM1 bits define the operating mode. The event count mode is used to count external events, which means the clock source comes from an external (TMR) pin. The timer mode functions as a normal timer with the clock source coming from the f_{INT} clock. The pulse width measurement mode can be used to count the high or low level duration of the external signal (TMR). The counting is based on the f_{INT} .

In the event count or timer mode, once the timer/event counter starts counting, it will count from the current contents in the timer/event counter to FFH. Once overflow occurs, the counter is reloaded from the timer/event counter preload register and generates the interrupt request flag (TF; bit 5 of INTC) at the same time.

Timer/Event Counter

In the pulse width measurement mode with the TON and TE bits equal to one, once the TMR has received a transient from low to high (or high to low if the TE bits is "0") it will start counting until the TMR returns to the original level and resets the TON. The measured result will remain in the timer/event counter even if the activated transient occurs again. In other words, only one cycle measurement can be done. Until setting the TON, the cycle measurement will function again as long as it receives further transient pulse. Note that, in this operating mode, the timer/event counter starts counting not according to the logic level but according to the transient edges. In the case of counter overflows, the counter is reloaded from the timer/event counter preload register and issues the interrupt request just like the other two modes. To enable the counting operation, the timer ON bit (TON; bit 4 of TMRC) should be set to 1. In the pulse width measurement mode, the TON will be cleared automatically after the measurement cycle is completed. But in the other two modes the TON can only be reset by instructions. The overflow of the timer/event counter is one of the wake-up sources. No matter what the operation mode is, writing a 0 to ETI can disable the interrupt service.

In the case of timer/event counter OFF condition, writing data to the timer/event counter preload register will also reload that data to the timer/event counter. But if the timer/event counter is turned on, data written to it will only be kept in the timer/event counter preload register. The timer/event counter will still operate until overflow occurs. When the timer/event counter (reading TMR) is read, the clock will be blocked to avoid errors. As clock blocking may results in a counting error, this must be taken into consideration by the programmer.

The bit0~bit2 of the TMRC can be used to define the pre-scaling stages of the internal clock sources of timer/event counter. The definitions are as shown. The overflow signal of timer/event counter can be used to generate the PFD signal.

Label (TMRC)	Bits	Function

TM0 TM1	6 7	To define the operating mode 01=Event count mode (external clock) 10=Timer mode (internal clock) 11=Pulse width measurement mode 00=Unused

TMRC register

Input/output ports

There are 19 bidirectional input/output lines in the microcontroller, labeled as PA, PB, PC and PD, which are mapped to the data memory of [12H], [14H], [16H] and [18H] respectively. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction "MOV A,[m]" (m=12H, 14H, 16H or 18H). For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

Input/output ports

Each I/O line has its own control register (PAC, PBC, PCC, PDC) to control the input/output configuration. With this control register, CMOS output or schmitt trigger input with or without pull-high resistor structures can be reconfigured dynamically (i.e. on-the-fly) under software control. To function as an input, the corresponding latch of the control register must write "1". The input source also depends on the control register. If the control register bit is "1", the input will read the pad state. If the control register bit is "0", the contents of the latches will move to the internal bus. The latter is possible in the "read-modify-write" instruction.

For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H and 19H.

After a chip reset, these input/output lines remain at high levels or floating state (dependent on pull-high options). Each bit of these input/output latches can be set or cleared by "SET [m].i" and "CLR [m].i" (m=12H, 14H, 16H or 18H) instructions.

Some instructions first input data and then follow the output operations. For example, "SET [m].i", "CLR [m].i", "CPL [m]", "CPLA [m]" read the entire port states into the CPU, execute the defined operations (bit-operation), and then write the results back to the latches or the accumulator.

Each line of port A has the capability of waking-up the device. The highest 6-bit of port C and 7-bit of port D are not physically implemented; on reading them a "0" is returned whereas writing then results in a no-operation. See Application note.

Each I/O port has a pull-high option. Once the pull-high option is selected, the I/O port has a pull-high resistor, otherwise, there's none. Take note that a non-pull-high I/O port operating in input mode will cause a floating state.

The PA3 is pin-shared with the PFD signal. If the PFD option is selected, the output signal in output mode of PA3 will be the PFD signal generated by timer/event counter overflow signal. The input mode always remaining its original functions. Once the PFD option is selected, the PFD output signal is controlled by PA3 data register only. The I/O functions of PA3 are shown below.

I/O	l/P	O/P	l/P	O/P
Mode	(Normal)	(Normal)	(PFD)	(PFD)
PA3	Logical Input	Logical Output	Logical Input	

Note: The PFD frequency is the timer/event counter overflow frequency divided by 2.

The PA5 and PA4 are pin-shared with INT and TMR pins respectively.

The PB can also be used as A/D converter inputs. The A/D function will be described later. There is a PWM function shared with PD0. If the PWM function is enabled, the PWM signal will appear on PD0 (if PD0 is operating in output mode). The I/O functions of PD0 is as shown.

I/O	l/P	O/P	I/P	O/P
Mode	(Normal)	(Normal)	(PWM)	(PWM)
PD0	Logical Input	Logical Output	Logical Input	

It is recommended that unused or not bonded out I/O lines should be set as output pins by software instruction to avoid consuming power under input floating state.

PWM

The microcontroller provides 1 channels (6+2)/(7+1) (dependent on options) bits PWM output shared with PD0. The PWM channel has its data registers denoted as PWM(1AH). The frequency source of the PWM counter comes from f_{SYS} . The PWM registers is a 8-bit register. The waveforms of PWM outputs are as shown. Once the PD0 is selected as the PWM outputs and the output function of PD0 is enabled (PDC.0="0"), writing 1 to PD0 data register will enable the PWM output function and writing "0" will force the PD0 to stay at "0".

A (6+2) bits mode PWM cycle is divided into four modulation cycles (modulation cycle 0~modulation cycle 3). Each modulation cycle has 64 PWM input clock period. In a (6+2) bit PWM function, the contents of the PWM register is divided into two groups. Group 1 of the PWM register is denoted by DC which is the value of PWM.7~PWM.2. The group 2 is denoted by AC which is the value of $PWM.1 \sim PWM.0$.

In a (6+2) bits mode PWM cycle, the duty cycle of each modulation cycle is shown in the table.

Parameter	AC (0~3)	Duty Cycle
Modulation cycle i (i=0~3)	i <ac< td=""><td>$\frac{\mathrm{DC}+1}{64}$</td></ac<>	$\frac{\mathrm{DC}+1}{64}$
	i≥AC	$\frac{\mathrm{DC}}{64}$

A (7+1) bits mode PWM cycle is divided into two modulation cycles (modulation cycle0~modulation cycle 1). Each modulation cycle has 128 PWM input clock period.

In a (7+1) bits PWM function, the contents of the PWM register is divided into two groups. Group 1 of the PWM register is denoted by DC which is the value of PWM.7~PWM.1.

The group 2 is denoted by AC which is the value of $\ensuremath{\mathsf{PWM.0.}}$

In a (7+1) bits mode PWM cycle, the duty cycle of each
modulation cycle is shown in the table.

Parameter	AC (0~1)	Duty Cycle
Modulation cycle i (i=0~1)	i <ac< td=""><td>$\frac{\mathrm{DC}+1}{128}$</td></ac<>	$\frac{\mathrm{DC}+1}{128}$
	i≥AC	$\frac{\text{DC}}{128}$

The modulation frequency, cycle frequency and cycle duty of the PWM output signal are summarized in the following table.

	PWM Cycle Frequency	PWM Cycle Duty
$f_{SYS}/64$ for (6+2) bits mode $f_{SYS}/128$ for (7+1) bits mode	f _{SYS} /256	[PWM]/256

A/D converter

The 8 channels and 9-bit resolution A/D (8-bit accuracy) converter are implemented in this microcontroller. The reference voltage is VDD. The A/D converter contains 4 special registers which are; ADRL (24H), ADRH (25H), ADCR (26H) and ACSR (27H). The ADRH and ADRL are A/D result register higher-order byte and lower-order byte and are read-only. After the A/D conversion is completed, the ADRH and ADRL should be read to get the conversion result data. The ADCR is an A/D converter control register, which defines the A/D channel number, analog channel select, start A/D conversion control bit and the end of A/D conversion flag. If the users want to start an A/D conversion. Define PB configuration, select the converted analog channel, and give START bit a raising edge and falling edge $(0\rightarrow 1\rightarrow 0)$. At the end of A/D conversion, the EOC bit is cleared and an A/D converter interrupt occurs (if the A/D converter interrupt is enabled). The ACSR is A/D clock setting register, which is used to select the A/D clock source.

The A/D converter control register is used to control the A/D converter. The bit2~bit0 of the ADCR are used to select an analog input channel. There are a total of eight channels to select. The bit5~bit3 of the ADCR are used to set PB configurations. PB can be an analog input or as digital I/O line decided by these 3 bits. Once a PB line is selected as an analog input, the I/O functions and

pull-high resistor of this I/O line are disabled and the A/D converter circuit is power on. The $\overline{\text{EOC}}$ bit (bit6 of the ADCR) is end of A/D conversion flag. Check this bit to know when A/D conversion is completed. The START bit of the ADCR is used to begin the conversion of the A/D converter. Giving START bit a rising edge and falling edge means that the A/D conversion has started. In order to ensure the A/D conversion is completed, the START should remain at "0" until the $\overline{\text{EOC}}$ is cleared to "0" (end of A/D conversion).

The bit 7 of the ACSR is used for testing purposes only. It can not be used by the users. The bit1 and bit0 of the ACSR are used to select A/D clock sources.

Label (ACSR)	Bits	Function
ADCS0 ADCS1	0 1	Selects the A/D converter clock source 00= system clock÷2 01= system clock÷8 10= system clock÷32 11= undefined
	2~6	Unused bit, read as "0"
TEST	7	For test mode used only

ACSR register

Label (ADCR)	Bits	Function
ACS0 ACS1 ACS2	0 1 2	Defines the analog channel select.
PCR0 PCR1 PCR2	3 4 5	Defines the port B configuration select. If PCR0, PCR1 and PCR2 are all zero, the ADC circuit is power off to reduce power consumption
EOC	6	Provides response at the end of the A/D conversion. (0= end of A/D conversion)
START	7	Starts the A/D conversion. $(0\rightarrow 1\rightarrow 0$ =start; $0\rightarrow 1\rightarrow$ reset A/D converter)

Note: "*" D0~D9 is A/D conversion result data bit LSB~MSB.

Low voltage reset – LVR

The microcontroller provides low voltage reset circuit in order to monitor the supply voltage of the device. If the supply voltage of the device is within the range 0.9V~3.3V, such as changing a battery, the LVR will automatically reset the device internally.

The LVR includes the following specifications:

- The low voltage (0.9V~3.3V) has to remain in their original state to exceed 1ms. If the low voltage state does not exceed 1ms, the LVR will ignore it and do not perform a reset function.
- The LVR uses the "OR" function with the external RES signal to perform chip reset.

The relationship between V_{DD} and V_{LVR} is shown below.

Note: V_{OPR} is the voltage range for proper chip operation at 4MHz system clock.

A/D conversion timing

- Note: *1: To make sure that the system oscillator has stabilized, the SST provides an extra delay of 1024 system clock pulses before entering the normal operation.
 - *2: Since low voltage state has to be maintained in its original state for over 1ms, therefore after 1ms delay, the device enters the reset mode.

I²C BUS Serial Interface

 I^2C BUS is implemented in the device. The I^2C BUS is a bidirectional two-wire lines. The data line and clock line are implement in SDA pin and SCL pin. The SDA and SCL are NMOS open drain output pin. They must connect a pull-high resistor respectively.

Using the I^2C BUS, the device has two ways to transfer data. One is in slave transmit mode, the other is in slave receive mode. There are four registers related to I^2C BUS; HADR([20H]), HCR([21H]), HSR([22H]), HDR([23H]). The HADR register is the slave address setting of the device, if the master sends the calling address which match, it means that this device is selected. The HCR is I^2C BUS control register which defines the device enable or disable the I^2C BUS as a transmitter or as a receiver. The HSR is I^2C BUS status register, it responds with the I^2C BUS status. The HDR is input/output data register, data to transmit or receive must be via the HDR register.

The I²C BUS control register contains three bits. The HEN bit define the enable or disable the I²C BUS. If the data wants transfer via I²C BUS, this bit must be set. The HTX bit defines whether the I²C BUS is in transmit or receive mode. If the device is as a transmitter, this bit must be set to "1". The TXAK defines the transmit acknowledge signal, when the device received 8-bit data, the device sends this bit to I²C BUS at the 9th clock. If the receiver wants to continue to receive the next data, this bit must be reset to "0" before receiving data.

The I^2C BUS status register contains 5 bits. The HCF bit is reset to "0" when one data byte is being transferred. If one data transfer is completed, this bit is set to "1". The

HASS bit is set "1" when the address is match, and the I²C BUS interrupt request flag is set to "1". If the interrupt is enabled and the stack is not full, a subroutine call to location 10H will occur. Writing data to the I²C BUS control register clears HAAS bit. If the address is not match, this bit is reset to "0". The HBB bit is set to respond the I²C BUS is busy. It mean that a START signal is detected. This bit is reset to "0" when the I²C BUS is not busy. It means that a STOP signal is detected and the I²C BUS is free. The SRW bit defines the read/write command bit, if the calling address is match. When HAAS is set to "1", the device check SRW bit to determine whether the device is working in transmit or receive mode. When SRW bit is set "1", it means that the master wants to read data from I²C BUS, the slave device must write data to I²C BUS, so the slave device is working in transmit mode. When SRW is reset to "0", it means that the master wants to write data to I²C BUS, the slave device must read data from the bus, so the slave device is working in receive mode. The RXAK bit is reset "0" indicates an acknowledges signal has been received. In the transmit mode, the transmitter checks RXAK bit to know the receiver which wants to receive the next data byte, so the transmitter continue to write data to the I²C BUS until the RXAK bit is set to "1" and the transmitter releases the SDA line, so that the master can send the STOP signal to release the bus.

The HADR bit7-bit1 define the device slave address. At the beginning of transfer, the master must select a device by sending the address of the slave device. The bit 0 is unused and is not defined. If the I^2C BUS receives a start signal, all slave device notice the continuity of the 8-bit data. The front of 7 bits is slave address and the

The I²C BUS initial program flow chart as follows:

first bit is MSB. If the address is match, the HAAS status bit is set and generate an I²C BUS interrupt. In the ISR, the slave device must check the HAAS bit to know the I²C BUS interrupt comes from the slave address that has match or completed one 8-bit data transfer. The last bit of the 8-bit data is read/write command bit, it responds in SRW bit. The slave will check the SRW bit to know if the master wants to transmit or receive data. The device check SRW bit to know it is as a transmitter or receiver.

Bit7~Bit1	Bit0
Slave Address	—

HADR register

Note: "-" means undefined

The HDR register is the I²C BUS input/output data register. Before transmitting data, the HDR must write the data which we want to transmit. Before receiving data, the device must dummy read data from HDR. Transmit or Receive data from I^2C BUS must be via the HDR register. At the beginning of the transfer of the I^2C BUS, the device must initial the bus, the following are the notes for initialing the I^2C BUS:

1: Write the I^2C BUS address register (HADR) to define its own slave address.

2: Set HEN bit of I²C BUS control register (HCR) bit 0 to enable the I²C BUS.

Label (HCR)	Bits	Function
HEN	7	To enable/disable I ² C BUS function (0= disable; 1= enable)
_	6~5	Unused bit, read as "0"

Label (HCR)	Bits	Function
нтх	4	To define the transmit/receive mode (0= receive mode; 1= transmit)
ТХАК	3	To enable/disable transmit acknowledge (0= acknowledge; 1= don't acknowledge)
	0~2	Unused bit, read as "0"

HCR register

3: Set EHI bit of the interrupt control register 1 (INTC1) bit 0 to enable the I^2C BUS interrupt.

Label (HSR)	Bits	Function
HCF	7	HCF is clear to "0" when one data byte is being transferred, HCF is set to "1" indi- cating 8-bit data communication has been finished.
HAAS	6	HAAS is set to "1" when the calling ad- dressed is matched, and I ² C BUS inter- rupt will occur and HIF is set.
НВВ	5	HBB is set to "1" when I^2C BUS is busy and HBB is cleared to "0" means that the I^2C BUS is not busy.
_	4	Unused bit, read as "0"
_	3	Unused bit, read as "0"
SRW	2	SRW is set to "1" when the master wants to read data from the I ² C BUS, so the slave must transmit data to the master. SRW is cleared to "0" when the master wants to write data to the I ² C BUS, so the slave must receive data from the master.
_	1	Unused bit, read as "0"
RXAK	0	RXAK is cleared to "0" when the master receives an 8-bit data and acknowledg- ment at the 9th clock, RXAK is set to "1" means not acknowledged.

HSR register

Start signal

The START signal is generated only by the master device. The other device in the bus must detect the START signal to set the I^2C BUS busy bit (HBB). The START signal is SDA line from high to low, when SCL is high.

Start bit

Slave address

The master must select a device for transferring the data by sending the slave device address after the START signal. All device in the I^2C BUS will receive the I^2C BUS slave address (7 bits) to compare with its own slave address (7 bits). If the slave address is matched, the slave device will generate an interrupt and save the following bit (8th bit) to SRW bit and sends an acknowledge bit (low level) to the 9th bit. The slave address is matched.

In interrupt subroutine, check HAAS bit to know whether the I²C BUS interrupt comes from a slave address that is matched or a data byte transfer is completed. When the slave address is matched, the device must be in transmit mode or receive mode and write data to HDR or dummy read from HDR to release the SCL line.

SRW bit

The SRW bit means that the master device wants to read from or write to the I²C BUS. The slave device check this bit to understand itself if it is a transmitter or a receiver. The SRW bit is set to "1" means that the master wants to read data from the I²C BUS, so the slave device must write data to a bus as a transmitter. The SRW is cleared to "0" means that the master wants to write data to the I²C BUS, so the slave device must read data from the I²C BUS, so the slave data from the I²C BUS as a receiver.

Acknowledge bit

One of the slave device generates an acknowledge signal, when the slave address is matched. The master device can check this acknowledge bit to know if the slave device accepts the calling address. If no acknowledge bit, the master must send a STOP bit and end the communication. When the l^2C BUS status register bit 6 HAAS is high, it means the address is matched, so the slave must check SRW as a transmitter (set HTX) to "1" or as a receiver (clear HTX) to "0".

Data byte

The data is 8 bits and is sent after the slave device has acknowledges the slave address. The first bit is MSB and the 8th bit is LSB. The receiver sends the acknowledge signal ("0") and continues to receive the next one byte data. If the transmitter checks and there's no acknowledge signal, then it release the SDA line, and the master sends a STOP signal to release the I²C BUS. The data is stored in the HDR register. The transmitter must write data to the HDR before transmit data and the receiver must read data from the HDR after receiving data.

The I²C BUS ISR program flow chart as follows:

S=Start (1 bit) SA=Slave Address (7 bits) SR=SRW bit (1 bit) M=Slave device send aclcnowledge bit (1 bit) D=Data (8 bits) A=ACK (RXAK bit for transmitter; TXAK bit for receiver 1 bit) P=Stop (1bit)

Data stable and data allow change

Receive acknowledge bit

When the receiver wants to continue to receive the next data byte, it generates an acknowledge bit (TXAK) at the 9th clock. The transmitter checks the acknowledge bit (RXAK) to continue to write data to the I^2C BUS or change to receive mode and dummy read the HDR register to release the SDA line and the master sends the STOP signal.

Stop bit

ROM code option

The following shows ten kinds of ROM code option in the HT46R22. ALL the ROM code options must be defined to ensure proper system function.

No.	ROM Code Option
1	OSC type selection. This option is to decide if an RC or crystal oscillator is chosen as system clock.
2	WDT source selection. There are three types of selection: on-chip RC oscillator, instruction clock or disable the WDT.
3	CLRWDT times selection. This option defines how to clear the WDT by instruction. "One time" means that the CLR WDT instruction can clear the WDT. "Two times" means only if both of the CLR WDT1 and CLR WDT2 instructions have been executed, then WDT can be cleared.
4	Wake-up selection. This option defines the wake-up function activity. External I/O pins (PA only) all have the capability to wake-up the chip from a HALT.
5	Pull-high selection. This option is to decide whether a pull-high resistance is visible or not in the input mode of the I/O ports. PA0~PA7, can be independently selected.
6	PFD selection: PA3: level output or PFD output
7	PWM selection: (7+1) or (6+2) mode PD0: level output or PWM output
8	WDT time-out period selection. There are four types of selection: WDT clock source divided by 2^{12} , 2^{13} , 2^{14} and 2^{15}
9	Low voltage reset selection: Enable or disable LVR function.
10	I ² C BUS selection: PA6 and PA7: I/O or I ² C BUS function

Application Circuits

Note: The resistance and capacitance for reset circuit should be designed to ensure that the VDD is stable and remains in a valid range of the operating voltage before bringing $\overline{\text{RES}}$ to high.

Instruction Set Summary

AND A,[m]	Logical AND accumulator with data memory
Description	Data in the accumulator and the specified data memory perform a tion. The result is stored in the accumulator.
Operation	$ACC \leftarrow ACC "AND" [m]$
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
AND A,x	Logical AND immediate data to the accumulator
Description	Data in the accumulator and the specified data perform a bitwise result is stored in the accumulator.
Operation	$ACC \leftarrow ACC "AND" x$
Affected flag(s)	
0()	TC2 TC1 TO PD OV Z AC C
ANDM A,[m]	Logical AND data memory with the accumulator
Description	Data in the specified data memory and the accumulator perform a tion. The result is stored in the data memory.
Operation	[m] ← ACC ″AND″ [m]
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
CALL addr	Subroutine call
Description	The instruction unconditionally calls a subroutine located at the gram counter increments once to obtain the address of the next onto the stack. The indicated address is then loaded. Program instruction at this address.
Operation	Stack \leftarrow PC+1 PC \leftarrow addr
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
CLR [m]	Clear data memory
Description	The contents of the specified data memory are cleared to 0.
Operation	[m] ← 00H
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C

		—			—	\checkmark	_	

CPLA [m]	Complement data memory and place result in the accumulator
Description	Each bit of the specified data memory is logically complemented (1's complement). Bits which previously contained a 1 are changed to 0 and vice-versa. The complemented result is stored in the accumulator and the contents of the data memory remain unchanged.
Operation	$ACC \leftarrow [\overline{m}]$
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
DAA [m]	Decimal-Adjust accumulator for addition
Description	The accumulator value is adjusted to the BCD (Binary Coded Decimal) code. The accumula-
	tor is divided into two nibbles. Each nibble is adjusted to the BCD code and an internal carry (AC1) will be done if the low nibble of the accumulator is greater than 9. The BCD adjustment
	is done by adding 6 to the original value if the original value is greater than 9 or a carry (AC or
	C) is set; otherwise the original value remains unchanged. The result is stored in the data memory and only the carry flag (C) may be affected.
Operation	If ACC.3~ACC.0 >9 or AC=1
operation	then [m].3~[m].0 \leftarrow (ACC.3~ACC.0)+6, AC1= \overline{AC}
	else [m].3~[m].0 ← (ACC.3~ACC.0), AC1=0
	and If ACC.7~ACC.4+AC1 >9 or C=1
	then [m].7~[m].4 ← ACC.7~ACC.4+6+AC1,C=1
	else [m].7~[m].4 \leftarrow ACC.7~ACC.4+AC1,C=C
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
DEC [m]	Decrement data memory
Description	Data in the specified data memory is decremented by 1.
Operation	[m] ← [m]−1
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
DECA [m]	Decrement data memory and place result in the accumulator
Description	Data in the specified data memory is decremented by 1, leaving the result in the accumulator.
Operation	The contents of the data memory remain unchanged.
Affected flag(s)	ACC ← [m]-1

SIZA [m]	Increment data memory and place result in ACC, skip if 0
Description	The contents of the specified data memory are incremented by 1. If the result is 0, the next in
	struction is skipped and the result is stored in the accumulator. The data memory remains un
	changed. If the result is 0, the following instruction, fetched during the current instruction execution, is discarded and a dummy cycle is replaced to get the proper instruction (2 cycles
	Otherwise proceed with the next instruction (1 cycle).
Operation	Skip if ([m]+1)=0, ACC ← ([m]+1)
Affected flag(s)	
	TC2 TC1 TO PD OV Z AC C
SNZ [m].i	Skip if bit i of the data memory is not 0
Description	If bit i of the specified data memory is not 0, the next instruction is skipped. If bit i of the data memory is not 0, the following instruction, fetched during the current instruction execution,
	discarded and a dummy cycle is replaced to get the proper instruction (2 cycles). Otherwis
	proceed with the next instruction (1 cycle).
Operation	Skip if [m].i≠0
