LOW SKEW, 1-TO-11 DIFFERENTIAL-TO-3.3V LVPECL
CLOCK MULTIPLIER / ZERO DELAY BUFFER

GENERAL DESCRIPTION

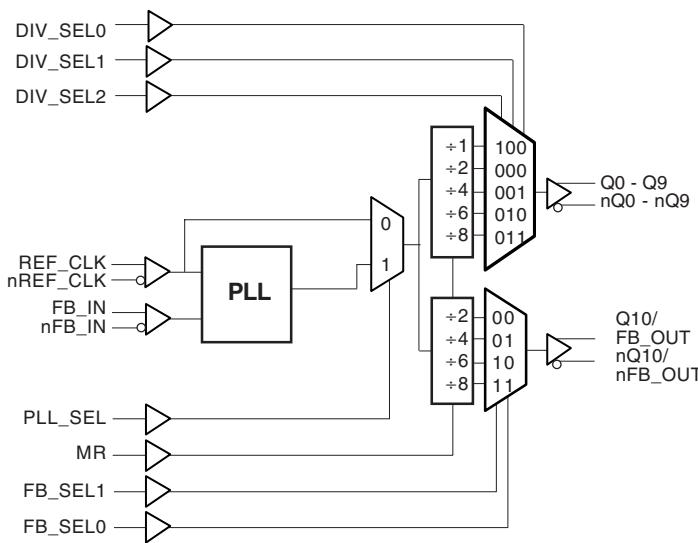

The ICS8731-01 is a low voltage, low skew, 1-to-11 Differential-to-3.3V LVPECL Clock Multiplier/Zero Delay Buffer and a member of the HiPerClockS™ family of High Performance Clock Solutions from ICS. With output frequencies up to 650MHz the ICS8731-01 is targeted at high performance clock applications. Along with a fully integrated PLL the ICS8731-01 contains frequency configurable, differential outputs and external feedback inputs for multiplying clock frequencies and regenerating clocks with "zero delay". Frequency multiplication is achieved by utilizing the separate feedback and clock output dividers. The value of the multiplier is determined by the ratio of the feedback divider, M, to the output divider, N. For multiplier values greater than 1, M must be greater than N. For multiplier values less than 1, M must be less than N. The zero delay mode is achieved with M and N at equal values. The divide values of the clock and feedback outputs are controlled by the DIV_SEL0:2 and FB_SEL0:1 inputs, respectively. The ICS8731-01 accepts any differential signal and translates it to differential 3.3V LVPECL output levels.

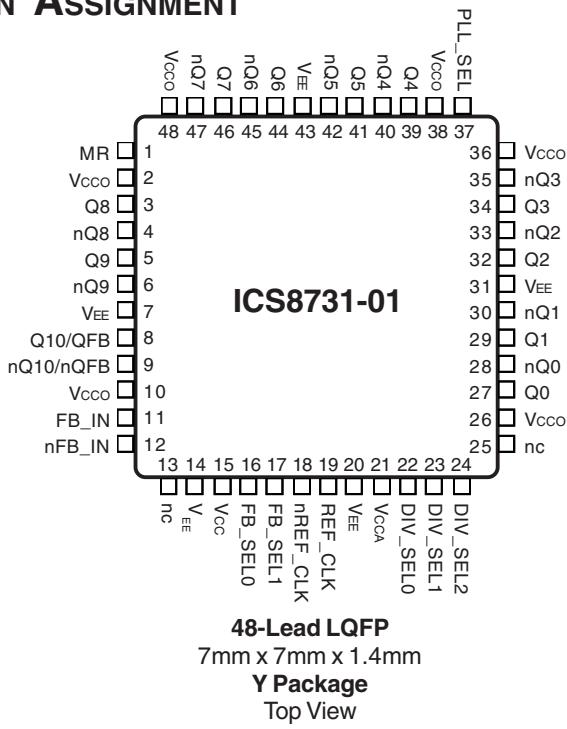

FEATURES

- 11 differential 3.3V LVPECL outputs
- Differential reference clock input pair
- REF_CLK, nREF_CLK pair can accept the following differential input levels: LVDS, LVPECL, L VHSTL, SSTL, HCSL
- Output frequency up to 650MHz
- Maximum reference clock input frequency: 250MHz
- Accepts any single-ended input signal with a resistor bias on nCLK input
- External feedback for zero delay capability
- Output skew: 200ps (maximum)
- Cycle-to-cycle jitter: 50ps (typical)
- Full 3.3V operating supply
- 0°C to 70°C ambient operating temperature

POWER CONSIDERATIONS

This section provides information on power dissipation and junction temperature for the ICS8731-01. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the ICS8731-01 is the sum of the core power plus the power dissipated in the load(s).

The following is the power dissipation for $V_{CC} = 3.3V + 5\% = 3.465V$, which gives worst case results.

NOTE: Please refer to Section 3 for details on calculating power dissipated in the load.

- Power (core)_{MAX} = $V_{CC_MAX} * I_{EE_MAX} = 3.465V * 130mA = 450.5mW$
- Power (outputs)_{MAX} = **30.2mW/Loaded Output pair**
If all outputs are loaded, the total power is $11 * 30.2mW = 332.2mW$

Total Power_{MAX} (3.465V, with all outputs switching) = $450.5mW + 332.2mW = 782.7mW$

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature for HiPerClockS™ devices is 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_total + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming a moderate air flow of 200 linear feet per minute and a multi-layer board, the appropriate value is 42.1°C/W per Table 8 below.

Therefore, T_j for an ambient temperature of 70°C with all outputs switching is:

$70^\circ C + 0.783W * 42.1^\circ C/W = 103^\circ C$. This is well below the limit of 125°C

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow, and the type of board (single layer or multi-layer).

TABLE 8. THERMAL RESISTANCE θ_{JA} FOR 48-PIN LQFP, FORCED CONVECTION

θ_{JA} by Velocity (Linear Feet per Minute)			
	0	200	500
Single-Layer PCB, JEDEC Standard Test Boards	67.8°C/W	55.9°C/W	50.1°C/W

3. Calculations and Equations.

The purpose of this section is to derive the power dissipated into the load.

LVPECL output driver circuit and termination are shown in *Figure 9*.

To calculate worst case power dissipation into the load, use the following equations which assume a 50Ω load, and a termination voltage of $V_{CCO} - 2V$.

- For logic high, $V_{OUT} = V_{OH_MAX} = V_{CCO_MAX} - 1.0V$

$$(V_{CCO_MAX} - V_{OH_MAX}) = 1.0V$$

- For logic low, $V_{OUT} = V_{OL_MAX} = V_{CCO_MAX} - 1.7V$

$$(V_{CCO_MAX} - V_{OL_MAX}) = 1.7V$$

Pd_H is power dissipation when the output drives high.

Pd_L is the power dissipation when the output drives low.

$$Pd_H = [(V_{OH_MAX} - (V_{CC_MAX} - 2V))/R_L] * (V_{CC_MAX} - V_{OH_MAX}) = [(2V - (V_{CC} - V_{OH_MAX}))/R_L] * (V_{CC} - V_{OH_MAX}) = [(2V - 1V)/50\Omega] * 1V = 20.0mW$$

$$Pd_L = [(V_{OL_MAX} - (V_{CC_MAX} - 2V))/R_L] * (V_{CC_MAX} - V_{OL_MAX}) = [(2V - (V_{CC} - V_{OL_MAX}))/R_L] * (V_{CC} - V_{OL_MAX}) = [(2V - 1.7V)/50\Omega] * 1.7V = 10.2mW$$

Total Power Dissipation per output pair = $Pd_H + Pd_L = 30.2mW$
