ICL8049

**Antilog Amplifier** 

July 1999

#### Features

- Temperature Compensated Operation .... 0°C to 70°C
- Scale Factor, Adjustable . . . . . . . . . . . . . 1V/Decade
- Dynamic Voltage Range ......60dB
- Dual JFET Input Op Amps

# Description

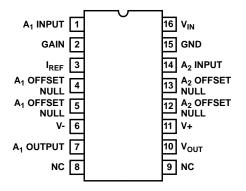

The ICL8049 is a monolithic antilogarithmic amplifier that is fully temperature compensated and is nominally designed to provide 1 decade of output voltage for each 1V change of input voltage. For increased flexibility, the scale factor, reference current and offset voltage are externally adjustable.

### Part Number Information

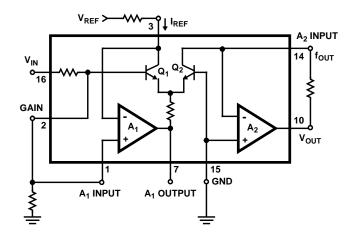

PART NUMBER	ERROR (25°C)	TEMPERATURE RANGE (°C)	PACKAGE			
ICL8049BCJE	10mV	0 to 70	16 Ld CERDIP			
ICL8049CCJE	25mV	0 to 70	16 Ld CERDIP

## ICL8049

## Absolute Maximum Ratings

### **Operating Conditions**

Supply Voltage
V <sub>IN</sub> (Input Current)
I <sub>REF</sub> (Reference Current) 2mA
Voltage Between Offset Null and V+ ±0.5V
Output Short Circuit Duration Indefinite
Power Dissipation
Lead Temperature (Soldering 10 Sec.)

Operating Temperature Range . . . . 0°C to 70°C Storage Temperature Range . . . -65°C to 150°C

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

**Electrical Specifications**  $V_S = \pm 15V$ ,  $T_A = 25^{\circ}C$ ,  $I_{REF} = 1$ mA, Scale Factor Adjusted for 1 Decade (Out) per Volt (In), Unless Otherwise Specified

		ICL4049BC		ICL8049CC				
PARAMETERS	TEST CONDITIONS	MIN	TYP	MAX	MIN	TYP	MAX	UNITS
Dynamic Range (V <sub>OUT</sub> )	V <sub>OUT</sub> = 10mV to 10V	60	-	-	60	-	-	dB
Error, Absolute Value	$0V \le V_{IN} \le 2V$	-	3	15	-	5	25	mV
	$T_{A} = 0^{o}C \text{ to } 70^{o}C,$ $0V \le V_{IN} \le 3V$	-	20	75	-	30	150	mV

# ICL8049 Detailed Description

The ICL8049 relies on the same logarithmic properties of the transistor as the ICL8048. The input voltage forces a specific  $\Delta V_{BE}$  between  $Q_1$  and  $Q_2$  (Figure 1). This  $V_{BE}$  difference is converted into a difference of collector currents by the transistor pair. The equation governing the behavior of the transistor pair is derived from (2) on the previous page and is as follows:

$$\frac{I_{C1}}{I_{C2}} = \exp\left[\frac{q\Delta V_{BE}}{kT}\right] \tag{1}$$

When numerical values for q/kT are put into this equation, it is found that a  $\Delta V_{BE}$  of 59mV (at +25°C) is required to change the collector current ratio by a factor of ten. But for ease of application, it is desirable that a 1V change at the input generate a tenfold change at the output. The required input attenuation is achieved by the network comprising  $R_1$  and  $R_2$ . In order that scale factors other than one decade per volt may be selected,  $R_2$  is external to the chip. It should have a value of  $1k\Omega$ , adjustable  $\pm20\%$ , for one decade per volt.  $R_1$  is a thin film resistor deposited on the monolithic chip; its temperature characteristics are chosen to compensate the temperature dependence of Equation 1, as explained on the previous page.

The overall transfer function is as follows:

$$\frac{I_{OUT}}{I_{REF}} = \exp\left[\frac{-R_2}{(R_1 + R_2)} \times \frac{qV_{IN}}{kT}\right]$$
 (2)

Substituting  $V_{OUT} = I_{OUT} \times R_{OUT}$  gives:

$$V_{OUT} = R_{OUT} I_{REF} exp \left[ \frac{-R_2}{(R_1 + R_2)} \times \frac{qV_{IN}}{kT} \right]$$
 (

For voltage references Equation 3 becomes

$$V_{OUT} = V_{REF} \times \frac{R_{OUT}}{R_{REF}} \exp \left[ \frac{-R_2}{(R_1 + R_2)} \times \frac{qV_{IN}}{kT} \right]$$
 (4)

# ICL8049 Offset and Scale Factor Adjustment

As with the log amplifier, the antilog amplifier requires three adjustments. The first step is to null out the offset voltage of  $A_2$ . This is accomplished by reverse biasing the base-emitter of  $Q_2$ .  $A_2$  then operates as a unity gain buffer with a grounded input. The second step forces  $V_{\text{IN}} = 0$ ; the output is adjusted for  $V_{\text{OUT}} = 10\text{V}$ . This step essentially "anchors" one point on the transfer function. The third step applies a specific input and adjusts the output to the correct voltage. This sets the scale factor. Referring to Figure 1 the exact procedure for 1 decade/volt is as follows:

- 1. Connect the input (pin #16) to +15V. This reverse biases the base-emitter of  $Q_2$ . Adjust  $R_7$  for  $V_{OUT} = 0V$ . Disconnect the input from +15V.
- Connect the input to Ground. Adjust R<sub>4</sub> for V<sub>OUT</sub> = 10V. Disconnect the input from Ground.
- 3. Connect the input to a precise 2V supply and adjust  $R_2$  for  $V_{OUT}$  = 100mV.

The procedure outlined above optimizes the performance over a 3 decade range at the output (i.e.,  $V_{OUT}$  from 10mV) to 10V). For a more limited range of output voltages, for example 1V to 10V, it would be better to use a precise 1V supply and adjust for  $V_{OUT}$  = 1V. For other scale factors and/or starting points, different values for  $R_2$  and  $R_{REF}$  will be needed, but the same basic procedure applies.
