**16M x 8 Bit / 8M x 16 Bit NAND Flash Memory****PRODUCT LIST**

Part Number	Vcc Range	Organization	PKG Type
K9F2808Q0C-B	1.65 ~ 1.95V	X8	TBGA
K9F2816Q0C-B		X16	
K9F2808U0C-Y	2.7 ~ 3.6V	X8	TSOP1
K9F2808U0C-B			TBGA
K9F2808U0C-V			WSOP1
K9F2816U0C-Y		X16	TSOP1
K9F2816U0C-B			TBGA

**FEATURES**

- Voltage Supply
  - 1.8V device(K9F28XXQ0C) : 1.65~1.95V
  - 3.3V device(K9F28XXU0C) : 2.7 ~ 3.6 V
- Organization
  - Memory Cell Array
    - X8 device(K9F2808X0C) : (16M + 512K)bit x 8bit
    - X16 device(K9F2816X0C) : (8M + 256K)bit x 16bit
  - Data Register
    - X8 device(K9F2808X0C) : (512 + 16)bit x 8bit
    - X16 device(K9F2816X0C) : (256 + 8)bit x 16bit
- Automatic Program and Erase
  - Page Program
    - X8 device(K9F2808X0C) : (512 + 16)Byte
    - X16 device(K9F2816X0C) : (256 + 8)Word
  - Block Erase :
    - X8 device(K9F2808X0C) : (16K + 512)Byte
    - X16 device(K9F2816X0C) : ( 8K + 256)Word
- Page Read Operation
  - Page Size
    - X8 device(K9F2808X0C) : (512 + 16)Byte
    - X16 device(K9F2816X0C) : (256 + 8)Word
  - Random Access : 10μs(Max.)
  - Serial Page Access : 50ns(Min.)
- Fast Write Cycle Time
  - Program time : 200μs(Typ.)
  - Block Erase Time : 2ms(Typ.)
- Command/Address/Data Multiplexed I/O Port
- Hardware Data Protection
  - Program/Erase Lockout During Power Transitions
- Reliable CMOS Floating-Gate Technology
  - Endurance : 100K Program/Erase Cycles
  - Data Retention : 10 Years
- Command Register Operation
- Intelligent Copy-Back
- Unique ID for Copyright Protection
- Package
  - K9F28XXU0C-YCB0/YIB0
  - 48 - Pin TSOP I (12 x 20 / 0.5 mm pitch)
  - K9F28XXX0C-BCB0/BIB0
  - 48- Ball TBGA ( 6 x 8.5 /0.8mm pitch , Width 1.0 mm)
  - K9F2808U0C-VCB0/VIB0
  - 48 - Pin WSOP I (12X17X0.7mm)
  - \* K9F2808U0C-V(WSOP I ) is the same device as K9F2808U0C-Y(TSOP1) except package type.

**GENERAL DESCRIPTION**

Offered in 16Mx8bit or 8Mx16bit, the K9F28XXX0C is 128M bit with spare 4M bit capacity. The device is offered in 1.8V or 3.3V Vcc. Its NAND cell provides the most cost-effective solution for the solid state mass storage market. A program operation programs the 528-byte(X8 device) or 264-word(X16 device) page in typical 200μs and an erase operation can be performed in typical 2ms on a 16K-byte(X8 device) or 8K-word(X16 device) block. Data in the page can be read out at 50ns cycle time per word. The I/O pins serve as the ports for address and data input/output as well as command input. The on-chip write control automates all program and erase functions including pulse repetition, where required, and internal verification and margining of data. Even the write-intensive systems can take advantage of the K9F28XXX0C's extended reliability of 100K program/erase cycles by providing ECC(Error Correcting Code) with real time mapping-out algorithm.

The K9F28XXX0C is an optimum solution for large nonvolatile storage applications such as solid state file storage and other portable applications requiring non-volatility.

## PIN DESCRIPTION

Pin Name	Pin Function
I/O <sub>0</sub> ~ I/O <sub>7</sub> (K9F2808X0C) I/O <sub>0</sub> ~ I/O <sub>15</sub> (K9F2816X0C)	<b>DATA INPUTS/OUTPUTS</b> The I/O pins are used to input command, address and data, and to output data during read operations. The I/O pins float to high-z when the chip is deselected or when the outputs are disabled. I/O <sub>8</sub> ~ I/O <sub>15</sub> are used only in X16 organization device. Since command input and address input are x8 operation, I/O <sub>8</sub> ~ I/O <sub>15</sub> are not used to input command & address. I/O <sub>8</sub> ~ I/O <sub>15</sub> are used only for data input and output.
CLE	<b>COMMAND LATCH ENABLE</b> The CLE input controls the activating path for commands sent to the command register. When active high, commands are latched into the command register through the I/O ports on the rising edge of the WE signal.
ALE	<b>ADDRESS LATCH ENABLE</b> The ALE input controls the activating path for address to the internal address registers. Addresses are latched on the rising edge of WE with ALE high.
$\overline{CE}$	<b>CHIP ENABLE</b> The $\overline{CE}$ input is the device selection control. When the device is in the Busy state, $\overline{CE}$ high is ignored, and the device does not return to standby mode.
$\overline{RE}$	<b>READ ENABLE</b> The $\overline{RE}$ input is the serial data-out control, and when active drives the data onto the I/O bus. Data is valid tREA after the falling edge of $\overline{RE}$ which also increments the internal column address counter by one.
$\overline{WE}$	<b>WRITE ENABLE</b> The $\overline{WE}$ input controls writes to the I/O port. Commands, address and data are latched on the rising edge of the WE pulse.
$\overline{WP}$	<b>WRITE PROTECT</b> The WP pin provides inadvertent write/erase protection during power transitions. The internal high voltage generator is reset when the WP pin is active low.
R/B	<b>READY/BUSY OUTPUT</b> The R/B output indicates the status of the device operation. When low, it indicates that a program, erase or random read operation is in process and returns to high state upon completion. It is an open drain output and does not float to high-z condition when the chip is deselected or when outputs are disabled.
VccQ	<b>OUTPUT BUFFER POWER</b> VccQ is the power supply for Output Buffer. VccQ is internally connected to Vcc, thus should be biased to Vcc.
Vcc	<b>POWER</b> Vcc is the power supply for device.
Vss	<b>GROUND</b>
N.C	<b>NO CONNECTION</b> Lead is not internally connected.
GND	<b>GND INPUT FOR ENABLING SPARE AREA</b> To do sequential read mode including spare area, connect this input pin to Vss or set to static low state or to do sequential read mode excluding spare area, connect this input pin to Vcc or set to static high state.
DNU	<b>DO NOT USE</b> Leave it disconnected.

**NOTE :** Connect all Vcc and Vss pins of each device to common power supply outputs.  
Do not leave Vcc or Vss disconnected.

NOTE : Column Address : Starting Address of the Register.

\* L must be set to "Low".

## PRODUCT INTRODUCTION

The K9F28XXX0C is a 132Mbit(138,412,032 bit) memory organized as 32,768 rows(pages) by 528(X8 device) or 264(X16 device) columns. Spare eight columns are located from column address of 512~527(X8 device) or 256~263(X16 device). A 528-byte(X8 device) or 264-word(X16 device) data register is connected to memory cell arrays accommodating data transfer between the I/O buffers and memory during page read and page program operations. The memory array is made up of 16 cells that are serially connected to form a NAND structure. Each of the 16 cells resides in a different page. A block consists of the 32 pages formed by two NAND structures, totaling 8448 NAND structures of 16 cells. The array organization is shown in Figure 2-1,2-2. The program and read operations are executed on a page basis, while the erase operation is executed on a block basis. The memory array consists of 2048 separately erasable 16K-Byte(X8 device) or 8K-Word(X16 device) blocks. It indicates that the bit by bit erase operation is prohibited on the K9F28XXX0C.

The K9F28XXX0C has addresses multiplexed into 8 I/Os(X16 device case : lower 8 I/Os). K9F2816X0C allows sixteen bit wide data transport into and out of page registers. This scheme dramatically reduces pin counts while providing high performance and allows systems upgrades to future densities by maintaining consistency in system board design. Command, address and data are all written through I/O's by bringing WE to low while CE is low. Data is latched on the rising edge of WE. Command Latch Enable(CLE) and Address Latch Enable(ALE) are used to multiplex command and address respectively, via the I/O pins. Some commands require one bus cycle. For example, Reset command, Read command, Status Read command, etc require just one cycle bus. Some other commands like Page Program and Copy-back Program and Block Erase, require two cycles: one cycle for setup and the other cycle for execution. The 32M-byte(X8 device) or 16M-word(X16 device) physical space requires 24 addresses, thereby requiring three cycles for word-level addressing: column address, low row address and high row address, in that order. Page Read and Page Program need the same three address cycles following the required command input. In Block Erase operation, however, only the two row address cycles are used. Device operations are selected by writing specific commands into the command register. Table 1 defines the specific commands of the K9F28XXX0C.

The device includes one block sized OTP(One Time Programmable), which can be used to increase system security or to provide identification capabilities. Detailed information can be obtained by contact with Samsung.

**Table 1. COMMAND SETS**

Function	1st. Cycle	2nd. Cycle	Acceptable Command during Busy
Read 1	00h/01h <sup>(1)</sup>	-	
Read 2	50h	-	
Read ID	90h	-	
Reset	FFh	-	O
Page Program	80h	10h	
Block Erase	60h	D0h	
Read Status	70h	-	O

**NOTE:** 1. The 00h command defines starting address of the 1st half of registers.

The 01h command defines starting address of the 2nd half of registers.

After data access on 2nd half of register by the 01h command, start pointer is automatically moved to 1st half register(00h) on the next cycle.

## ABSOLUTE MAXIMUM RATINGS

Parameter		Symbol	Rating		Unit
			K9F28XXQ0C(1.8V)	K9F28XXU0C(3.3V)	
Voltage on any pin relative to Vss		V <sub>IN/OUT</sub>	-0.6 to + 2.45	-0.6 to + 4.6	V
		V <sub>CC</sub>	-0.2 to + 2.45	-0.6 to + 4.6	
		V <sub>CCQ</sub>	-0.2 to + 2.45	-0.6 to + 4.6	
Temperature Under Bias	K9F28XXX0C-YCB0,BCB0	T <sub>BIAS</sub>	-10 to +125		°C
	K9F28XXX0C-YIB0,BIB0		-40 to +125		
Storage Temperature	K9F28XXX0C-YCB0,BCB0	T <sub>STG</sub>	-65 to +150		°C
	K9F28XXX0C-YIB0,BIB0				
Short Circuit Current		I <sub>OS</sub>	5		mA

### NOTE :

- Minimum DC voltage is -0.6V on input/output pins. During transitions, this level may undershoot to -2.0V for periods <30ns. Maximum DC voltage on input/output pins is V<sub>CC</sub>+0.3V which, during transitions, may overshoot to V<sub>CC</sub>+2.0V for periods <20ns.
- Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to the conditions as detailed in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

## RECOMMENDED OPERATING CONDITIONS

(Voltage reference to GND, K9F28XX0C-YCB0,BCB0 :T<sub>A</sub>=0 to 70°C, K9F28XX0C-YIB0,BIB0:T<sub>A</sub>=-40 to 85°C)

Parameter	Symbol	K9F28XXQ0C(1.8V)			K9F28XXU0C(3.3V)			Unit
		Min	Typ.	Max	Min	Typ.	Max	
Supply Voltage	V <sub>CC</sub>	1.65	1.8	1.95	2.7	3.3	3.6	V

## FLASH MEMORY

## VALID BLOCK

Parameter	Symbol	Min	Typ.	Max	Unit
Valid Block Number	NvB	1004	-	1024	Blocks

## NOTE :

1. The K9F28XXX0C may include invalid blocks when first shipped. Additional invalid blocks may develop while being used. The number of valid blocks is presented with both cases of invalid blocks considered. Invalid blocks are defined as blocks that contain one or more bad bits. Do not erase or program factory-marked bad blocks. Refer to the attached technical notes for a appropriate management of invalid blocks.
2. The 1st block, which is placed on 00h block address, is fully guaranteed to be a valid block, does not require Error Correction.

## AC TEST CONDITION

(K9F28XXX0C-YCB0,BCB0 :TA=0 to 70°C, K9F28XXX0C-YIB0,BIB0:TA=-40 to 85°C

K9F28XXQ0C : Vcc=1.65V~1.95V , K9F28XXU0C : Vcc=2.7V~3.6V unless otherwise noted)

Parameter	K9F28XXQ0C	K9F28XXU0C
Input Pulse Levels	0V to VccQ	0.4V to 2.4V
Input Rise and Fall Times	5ns	5ns
Input and Output Timing Levels	VccQ/2	1.5V
K9F28XXQ0C:Output Load (VccQ:1.8V +/-10%) K9F28XXU0C:Output Load (VccQ:3.0V +/-10%)	1 TTL GATE and CL=30pF	1 TTL GATE and CL=50pF
K9F28XXU0C:Output Load (VccQ:3.3V +/-10%)	-	1 TTL GATE and CL=100pF

## CAPACITANCE(TA=25°C, Vcc=1.8V/3.3V, f=1.0MHz)

Item	Symbol	Test Condition	Min	Max	Unit
Input/Output Capacitance	C <sub>I/O</sub>	V <sub>IL</sub> =0V	-	10	pF
Input Capacitance	C <sub>IN</sub>	V <sub>IN</sub> =0V	-	10	pF

NOTE : Capacitance is periodically sampled and not 100% tested.

## MODE SELECTION

CLE	ALE	$\overline{\text{CE}}$	$\overline{\text{WE}}$	$\overline{\text{RE}}$	GND	$\overline{\text{WP}}$	Mode	
H	L	L		H	X	X	Read Mode	Command Input

Device Resetting Time(Read/Program/Erase)		tRST	-	5/10/500 <sup>(1)</sup>	-	5/10/500 <sup>(1)</sup>	μs
K9F2808U0C-Y only	Last RE High to Busy (at sequential read)	tRB	-	100	-	100	ns
	$\overline{\text{CE}}$ High to Ready(in case of inter-ception by $\overline{\text{CE}}$ at read)	tCRY	-	50 +tr(R/ $\overline{\text{B}}$ ) <sup>(3)</sup>	-	50 +tr(R/ $\overline{\text{B}}$ ) <sup>(3)</sup>	ns
	$\overline{\text{CE}}$ High Hold Time(at the last serial read) <sup>(2)</sup>	tCEH	100	-	100	-	ns

**NOTE :**

1. If reset command(FFh) is written at Ready state, the device goes into Busy for maximum 5us.
2. To break the sequential read cycle, CE must be held high for longer time than tCEH.
3. The time to Ready depends on the value of the pull-up resistor tied R/B pin.

## NAND Flash Technical Notes

### Invalid Block(s)

Invalid blocks are defined as blocks that contain one or more invalid bits whose reliability is not guaranteed by Samsung. The information regarding the invalid block(s) is so called as the invalid block information. Devices with invalid block(s) have the same quality level as devices with all valid blocks and have the same AC and DC characteristics. An invalid block(s) does not affect the performance of valid block(s) because it is isolated from the bit line and the common source line by a select transistor. The system design must be able to mask out the invalid block(s) via address mapping. The 1st block, which is placed on 00h block address, is fully guaranteed to be a valid block, does not require Error Correction.

### Identifying Invalid Block(s)

All device locations are erased(FFh) except locations where the invalid block(s) information is written prior to shipping. The invalid block(s) status is defined by the 6th byte(X8 device) or 1st & 6th word(X16 device) in the spare area. Samsung makes sure that either the 1st or 2nd page of every invalid block has non-FFh(X8 device) or non-FFFFh(X16 device) data at the column address of 517(X8 device) or 256 and 261(X16 device). Since the invalid block information is also erasable in most cases, it is impossible to recover the information once it has been erased. Therefore, the system must be able to recognize the invalid block(s) based on the original invalid block information and create the invalid block table via the following suggested flow chart(Figure 3). Any intentional erasure of the original invalid block information is prohibited.

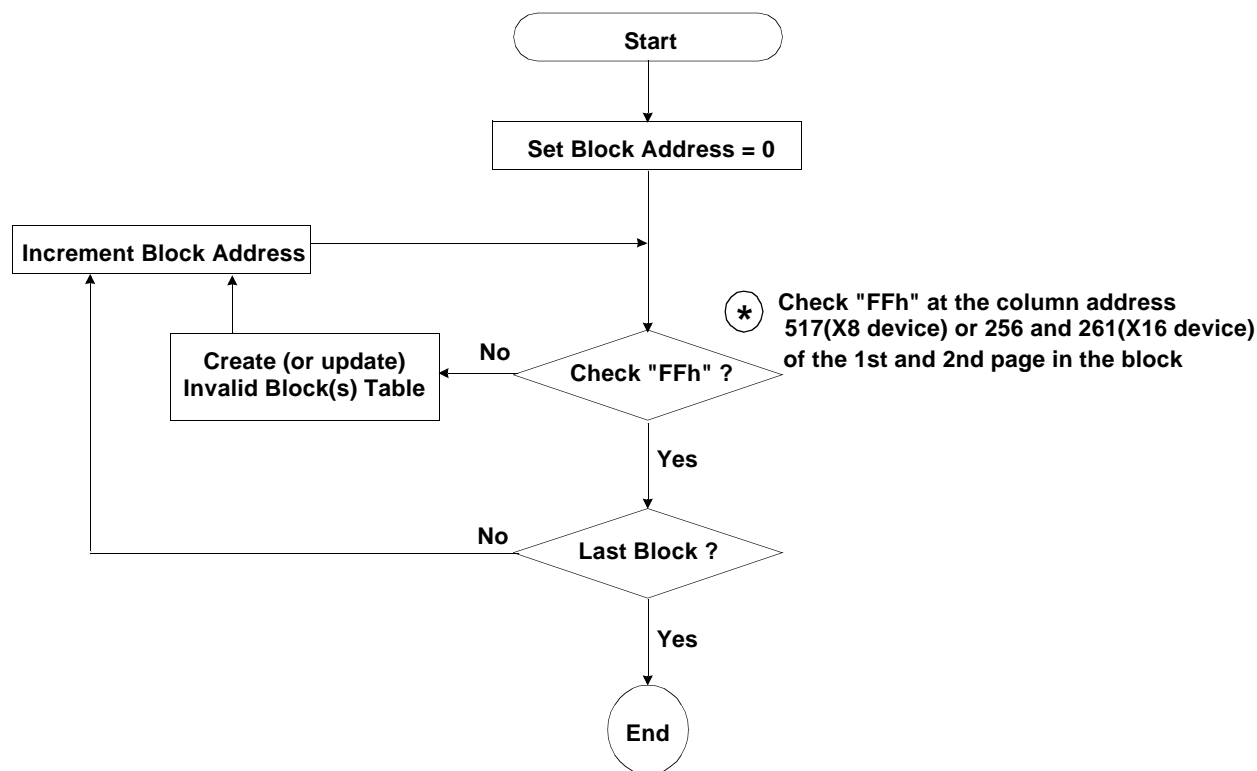

Figure 3. Flow chart to create invalid block table.

## NAND Flash Technical Notes (Continued)

### Error in write or read operation

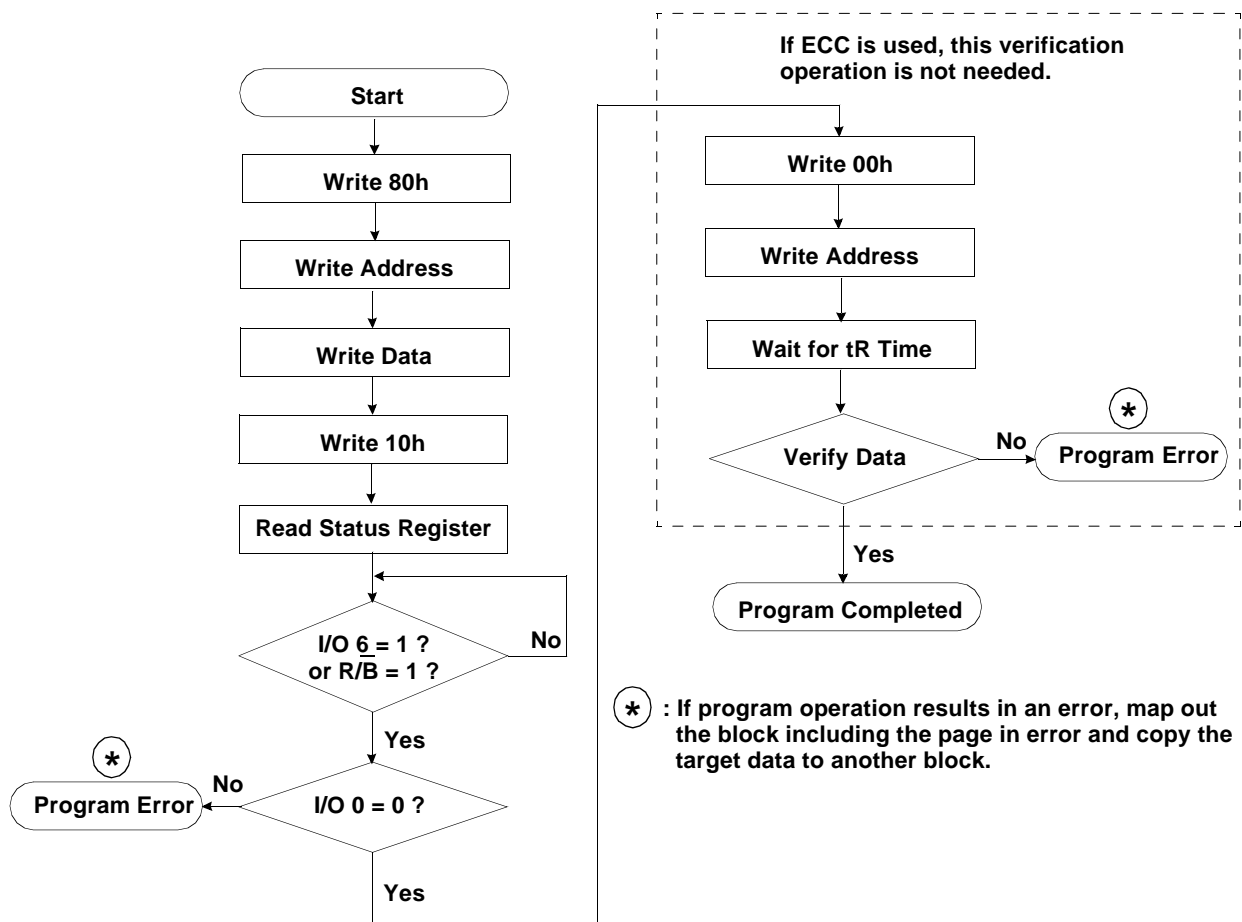

Over its life time, the additional invalid blocks may develop with NAND Flash memory. Refer to the qualification report for the actual data. The following possible failure modes should be considered to implement a highly reliable system. In the case of status read failure after erase or program, block replacement should be done. Because program status fail during a page program does not affect the data of the other pages in the same block, block replacement can be executed with a page-sized buffer by finding an erased empty block and reprogramming the current target data and copying the rest of the replaced block. To improve the efficiency of memory space, it is recommended that the read or verification failure due to single bit error be reclaimed by ECC without any block replacement. The said additional block failure rate does not include those reclaimed blocks.

Failure Mode		Detection and Countermeasure sequence
Write	Erase Failure	Status Read after Erase --> Block Replacement
	Program Failure	Status Read after Program --> Block Replacement Read back ( Verify after Program) --> Block Replacement or ECC Correction
Read	Single Bit Failure	Verify ECC --> ECC Correction

### ECC

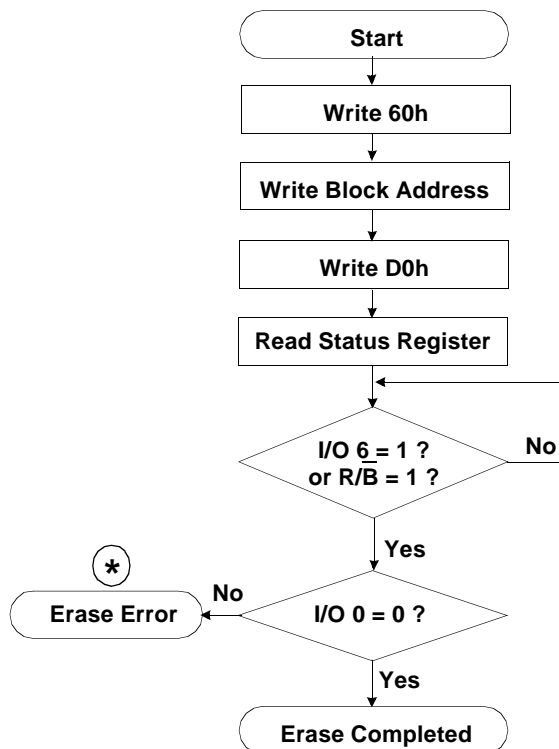

: Error Correcting Code --> Hamming Code etc.  
Example) 1bit correction & 2bit detection

### Program Flow Chart

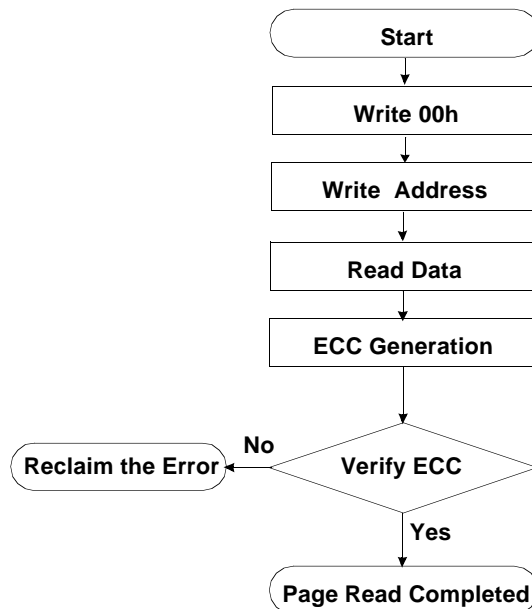

## NAND Flash Technical Notes (Continued)

### Erase Flow Chart

### Read Flow Chart

\* : If erase operation results in an error, map out the failing block and replace it with another block.

### Block Replacement

\* Step1

When an error happens in the nth page of the Block A'during erase or program operation.

\* Step2

Copy the nth page data of the Block A'in the buffer memory to the nth page of another free block. (Block B)

\* Step3

Then, copy the data in the 1st ~ (n-1)th page to the same location of the Block B'

\* Step4

Do not further erase Block A'by creating an Invalid Block'table or other appropriate scheme.

## Pointer Operation of K9F2808X0C(X8)

Samsung NAND Flash has three address pointer commands as a substitute for the two most significant column addresses. 00h' command sets the pointer to A'area(0~255byte), 01h'command sets the pointer to B'area(256~511byte), and 50h'command sets the pointer to C' area(512~527byte). With these commands, the starting column address can be set to any of a whole page(0~527byte). 00h'or 50h'is sustained until another address pointer command is inputted. 01h'command, however, is effective only for one operation. After any operation of Read, Program, Erase, Reset, Power\_Up is executed once with 01h'command, the address pointer returns to A'area by itself. To program data starting from A'or C'area, 00h'or 50h'command must be inputted before 80h'command is written. A complete read operation prior to 80h'command is not necessary. To program data starting from B'area, 01h'command must be inputted right before 80h'command is written.

Table 1. Destination of the pointer

Command	Pointer position	Area
00h	0 ~ 255 byte	1st half array(A)
01h	256 ~ 511 byte	2nd half array(B)
50h	512 ~ 527 byte	spare array(C)

Figure 2. Block Diagram of Pointer Operation

### (1) Command input sequence for programming 'A'area

### (2) Command input sequence for programming B'area

### (3) Command input sequence for programming C'area

### Pointer Operation of K9F2816X0C(X16)

Samsung NAND Flash has two address pointer commands as a substitute for the most significant column address. 00h'command sets the pointer to A'area(0~255word), and 50h'command sets the pointer to B'area(256~263word). With these commands, the starting column address can be set to any of a whole page(0~263word). 00h'or 50h'is sustained until another address pointer command is inputted. To program data starting from A'or B'area, 00h'or 50h'command must be inputted before 80h'command is written. A complete read operation prior to 80h'command is not necessary.

Table 1. Destination of the pointer

Command	Pointer position	Area
00h	0 ~ 255 word	main array(A)
50h	256 ~ 263 word	spare array(B)

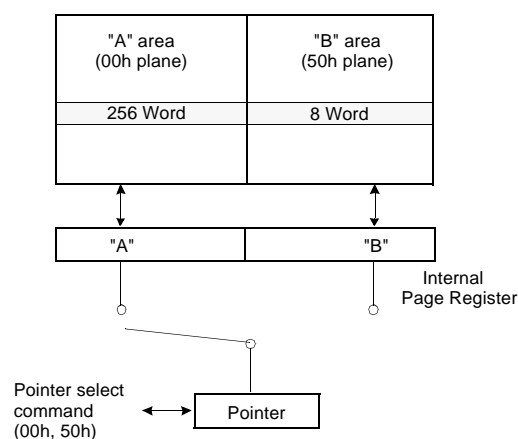

Figure 4. Block Diagram of Pointer Operation

#### (1) Command input sequence for programming 'A'area

#### (2) Command input sequence for programming B'area

### System Interface Using $\overline{\text{CE}}$ dont-care.

For an easier system interface,  $\overline{\text{CE}}$  may be inactive during the data-loading or sequential data-reading as shown below. The internal 528byte/264word page registers are utilized as separate buffers for this operation and the system design gets more flexible. In addition, for voice or audio applications which use slow cycle time on the order of u-seconds, de-activating  $\overline{\text{CE}}$  during the data-loading and reading would provide significant savings in power consumption.

Figure 5. Program Operation with  $\overline{\text{CE}}$  dont-care.

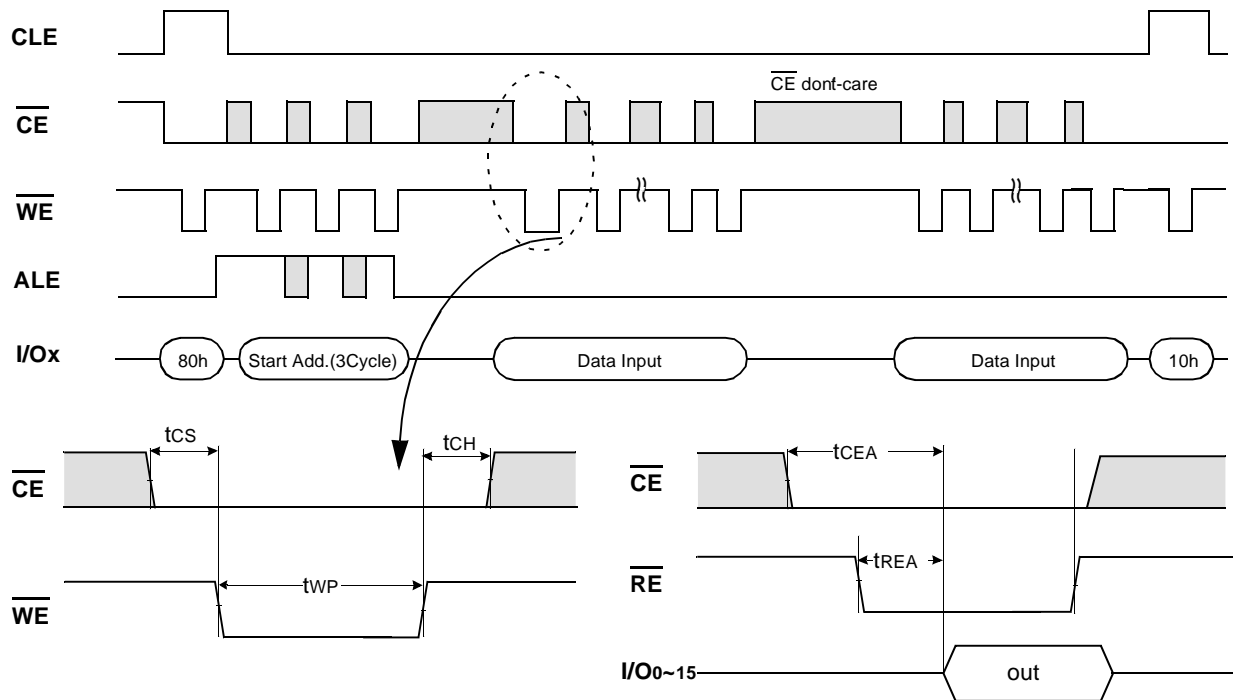

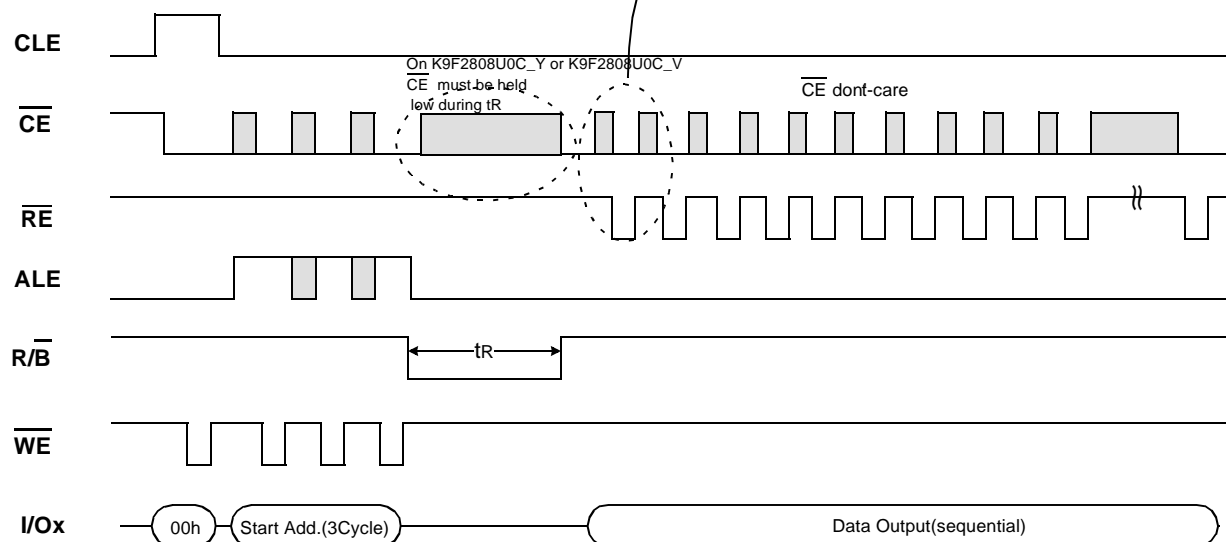

Figure 6. Read Operation with  $\overline{\text{CE}}$  dont-care.

## FLASH MEMORY

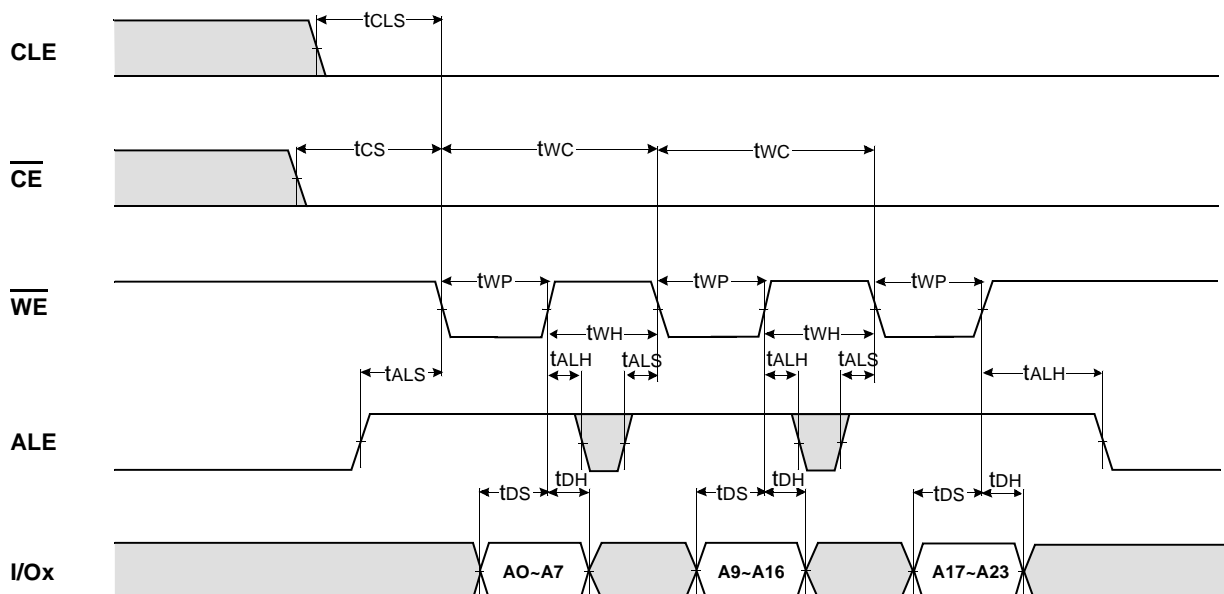

Device	I/O	DATA
	I/Ox	Data In/Out
K9F2808X0C(X8 device)	I/O 0 ~ I/O 7	~528byte
K9F2816X0C(X16 device)	I/O 0 ~ I/O 15 <sup>1)</sup>	~264word

NOTE: 1. I/O8~15 must be set to "0" during command or address input.  
2. I/O8~15 are used only for data bus.

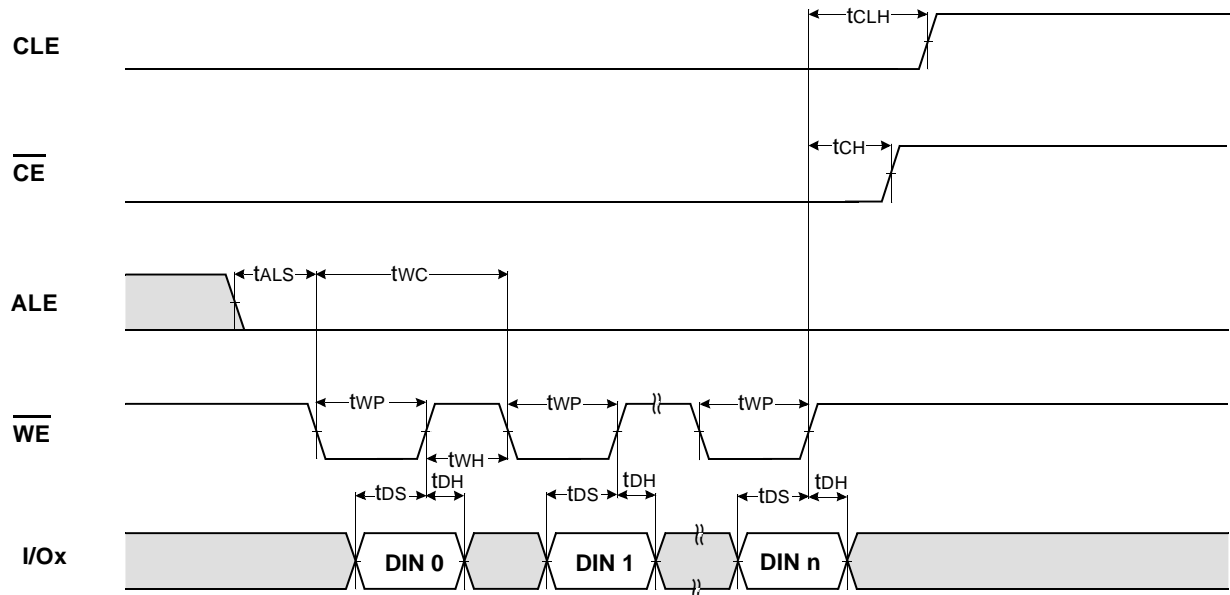

### \* Command Latch Cycle

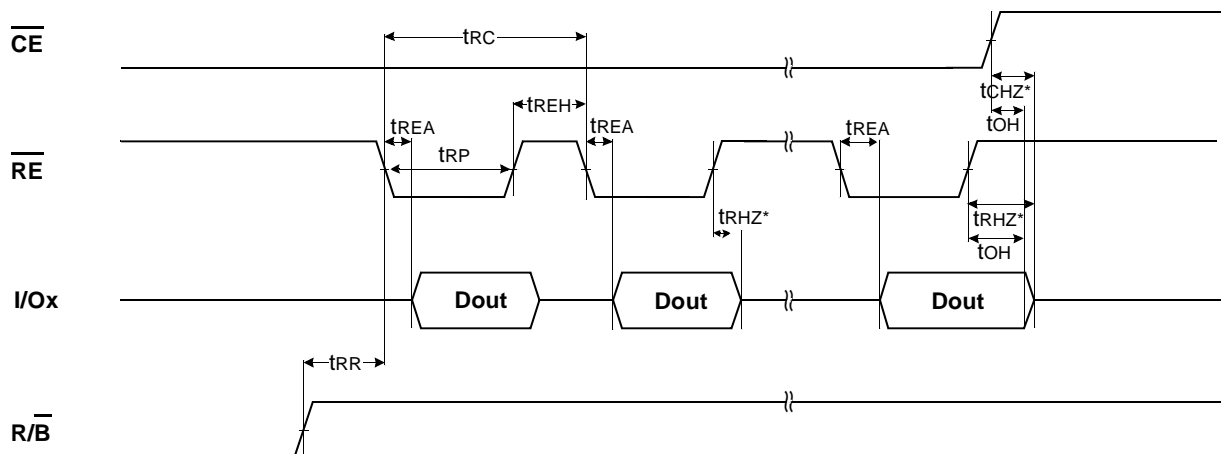

### \* Address Latch Cycle

\* Input Data Latch Cycle

\* Sequential Out Cycle after Read (CLE=L, WE=H, ALE=L)

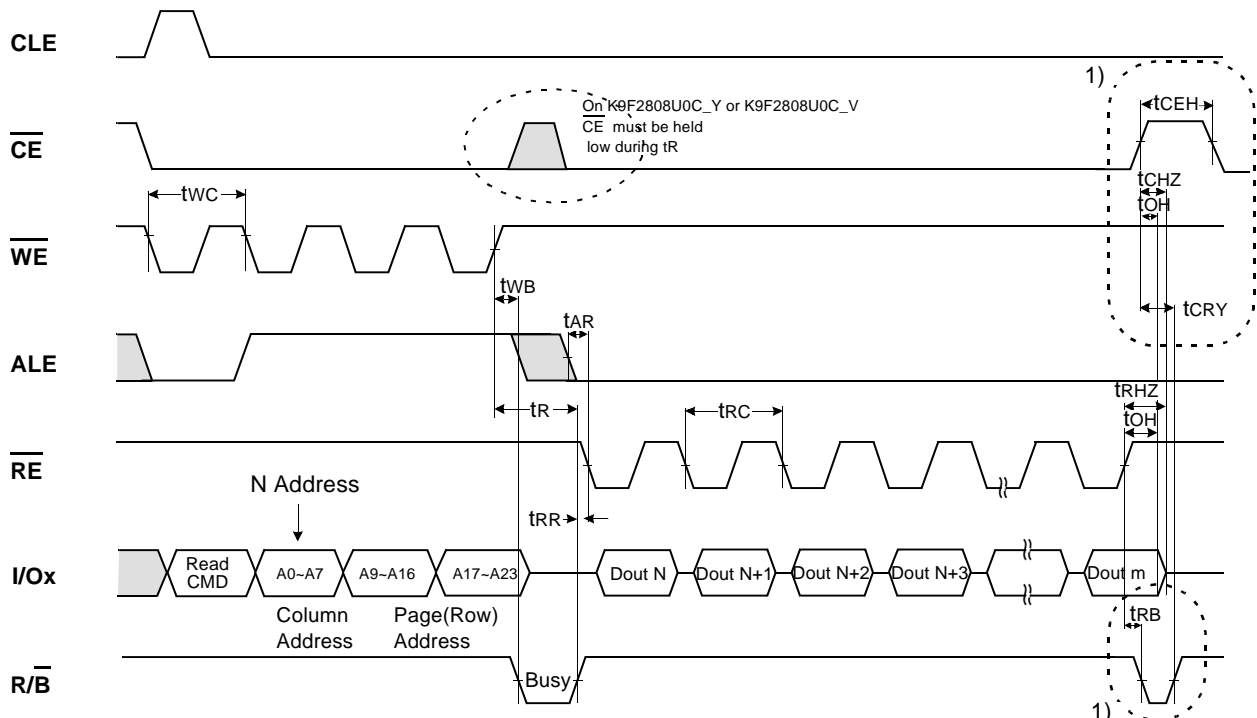

NOTES : Transition is measured  $\pm 200\text{mV}$  from steady state voltage with load.  
This parameter is sampled and not 100% tested.

\* Status Read Cycle

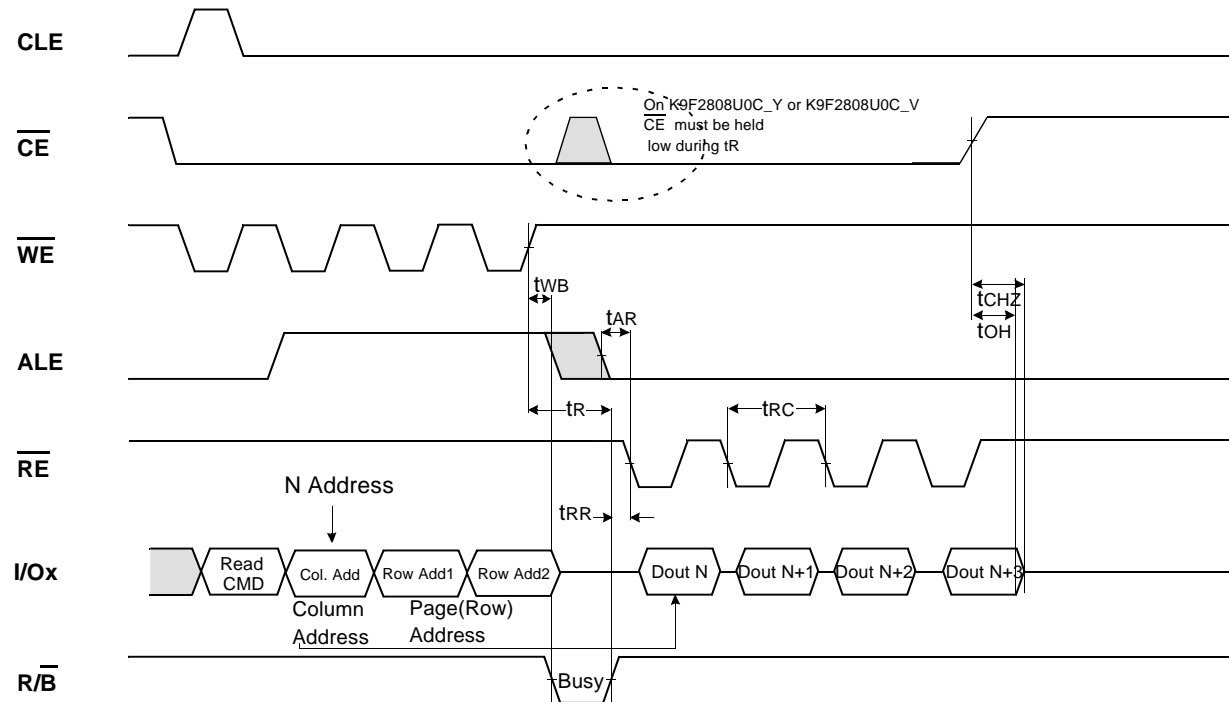

READ1 OPERATION (READ ONE PAGE)

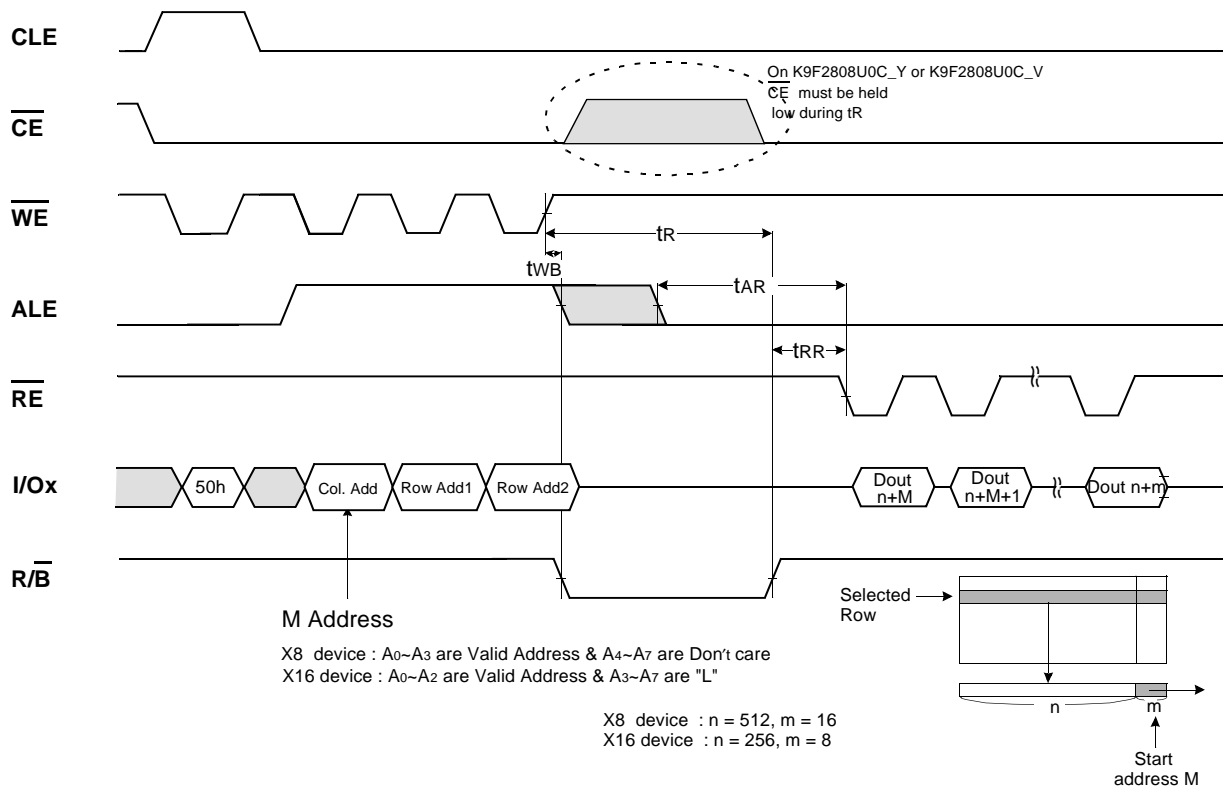

X8 device : m = 528 , Read CMD = 00h or 01h  
X16 device : m = 264 , Read CMD = 00h

NOTES : 1) is only valid on K9F2808U0C\_Y or K9F2808U0C\_V

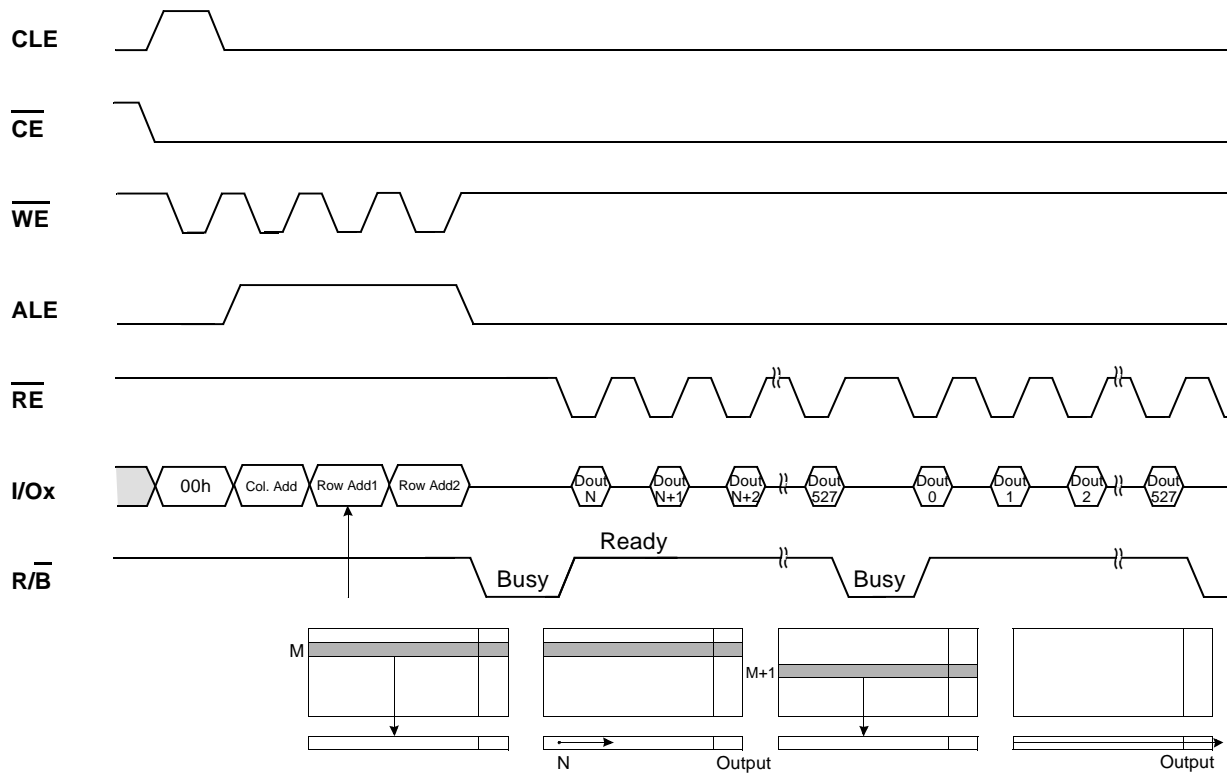

## READ1 OPERATION (INTERCEPTED BY $\overline{CE}$ )

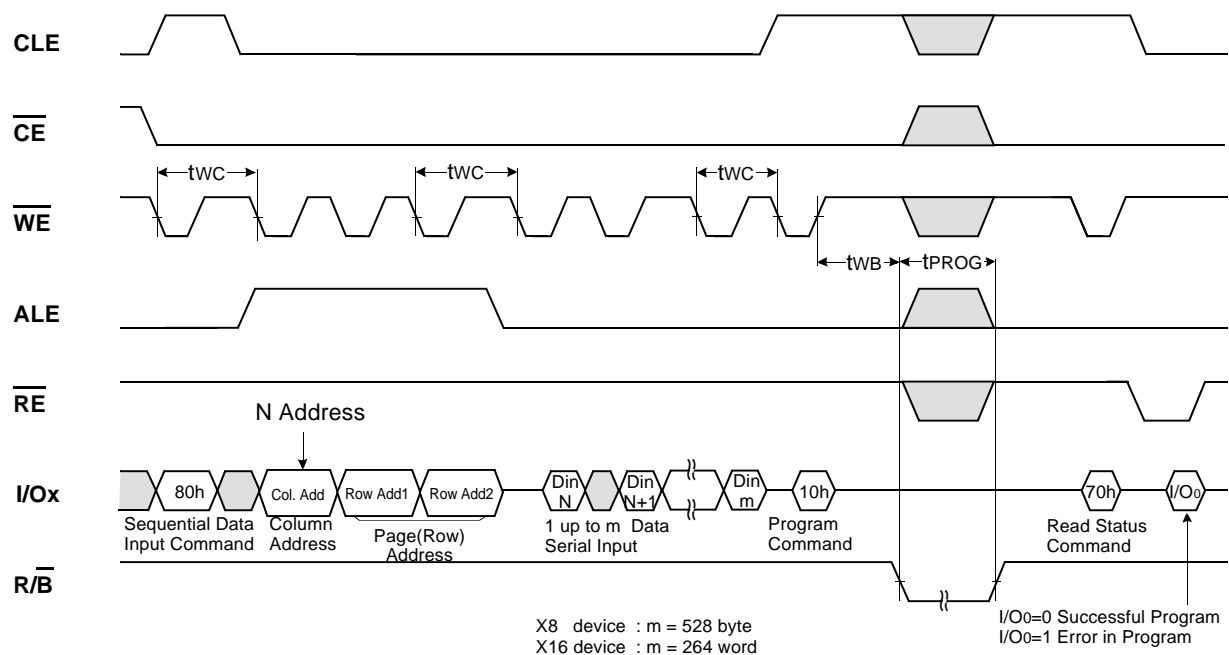

## READ2 OPERATION (READ ONE PAGE)

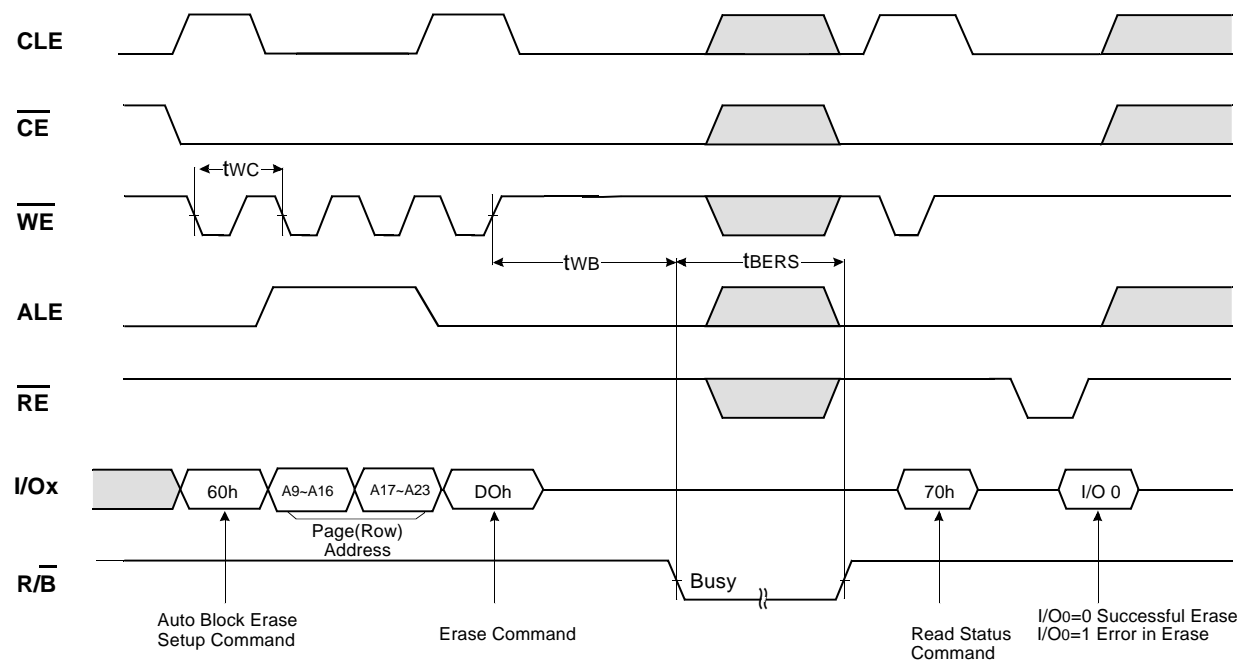

## SEQUENTIAL ROW READ OPERATION (only for K9F2808U0C-Y or K9F2808U0C-V)

## PAGE PROGRAM OPERATION

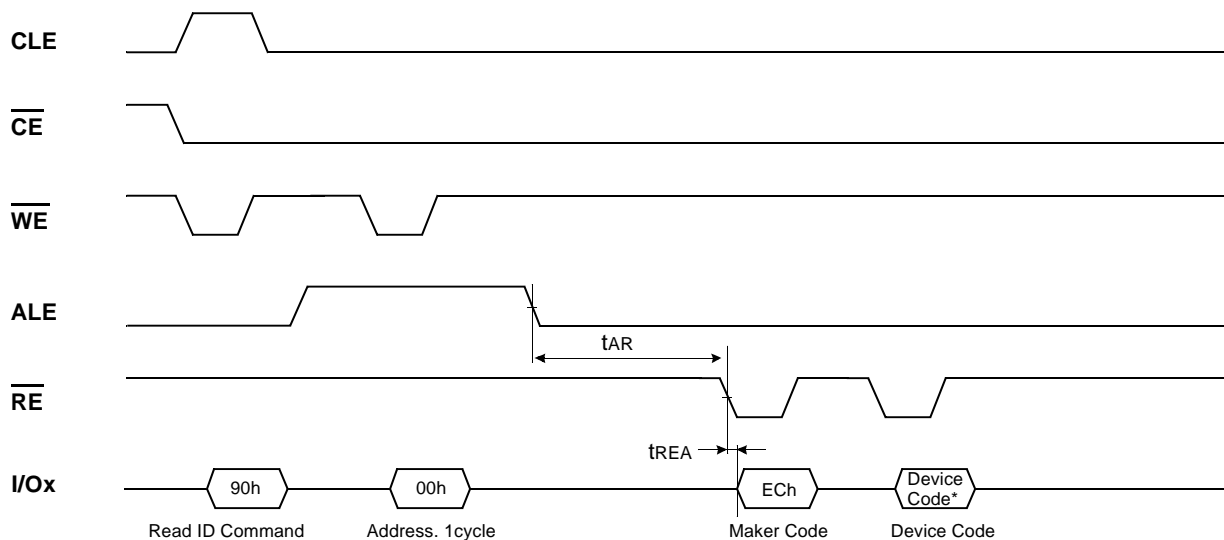

## BLOCK ERASE OPERATION (ERASE ONE BLOCK)

## MANUFACTURE & DEVICE ID READ OPERATION

Device	Device Code*
K9F2808Q0C	33h
K9F2808U0C	73h
K9F2816Q0C	XX43h
K9F2816U0C	XX53h

## DEVICE OPERATION

### PAGE READ

Upon initial device power up, the device defaults to Read1 mode. This operation is also initiated by writing 00h to the command register along with three address cycles. Once the command is latched, it does not need to be written for the following page read operation. Two types of operations are available : random read, serial page read.

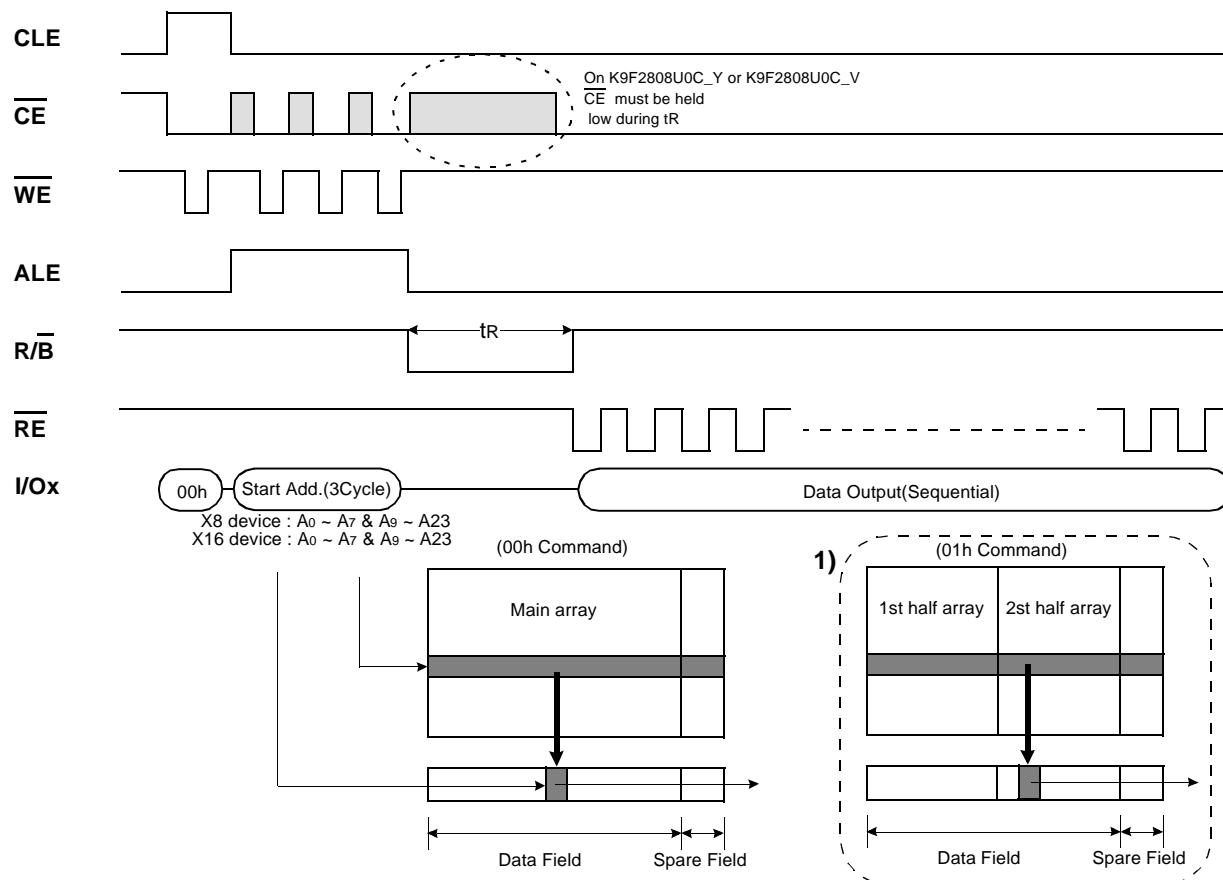

The random read mode is enabled when the page address is changed. The 528 bytes(X8 device) or 264 words(X16 device) of data within the selected page are transferred to the data registers in less than 10 $\mu$ s( $t_R$ ). The system controller can detect the completion of this data transfer( $t_R$ ) by analyzing the output of R/B pin. Once the data in a page is loaded into the registers, they may be read out in 50ns cycle time by sequentially pulsing  $\overline{RE}$ . High to low transitions of the  $\overline{RE}$  clock output the data starting from the selected column address up to the last column address[column 511/ 527(X8 device) 255 /263(X16 device) depending on the state of GND input pin].

The way the Read1 and Read2 commands work is like a pointer set to either the main area or the spare area. The spare area of 512 ~527 bytes(X8 device) or 256~263 words(X16 device) may be selectively accessed by writing the Read2 command with GND input pin low. Addresses A0-A3(X8 device) or A0-A2(X16 device) set the starting address of the spare area while addresses A4~A7 are ignored in X8 device case or A3-A7 must be "L" in X16 device case. The Read1 command is needed to move the pointer back to the main area. Figures 7, 8 show typical sequence and timings for each read operation.

### Sequential Row Read is available only on K9F2808U0C\_Y or K9F2808U0C\_V :

After the data of last column address is clocked out, the next page is automatically selected for sequential row read. Waiting 10 $\mu$ s again allows reading the selected page. The sequential row read operation is terminated by bringing  $\overline{CE}$  high. Unless the operation is aborted, the page address is automatically incremented for sequential row read as in Read1 operation and spare sixteen bytes of each page may be sequentially read. The Sequential Read 1 and 2 operation is allowed only within a block and after the last page of a block is readout, the sequential read operation must be terminated by bringing  $\overline{CE}$  high. When the page address moves onto the next block, read command and address must be given. Figures 7-1, 8-1 show typical sequence and timings for sequential row read operation.

Figure 7. Read1 Operation

NOTE: 1) After data access on 2nd half array by 01h command, the start pointer is automatically moved to 1st half array (00h) at next cycle. 01h command is only available on X8 device(K9F2808X0C).

**Figure 8-1. Sequential Row Read2 Operation (GND Input=Fixed Low)** (only for K9F2808U0C-Y or K9F2808U0C-V)

## PAGE PROGRAM

The device is programmed basically on a page basis, but it does allow multiple partial page programming of a byte/word or consecutive bytes/words up to 528(X8 device) or 264(X16 device), in a single page program cycle. The number of consecutive partial page programming operation within the same page without an intervening erase operation should not exceed 2 for main array and 3 for spare array. The addressing may be done in any random order in a block. A page program cycle consists of a serial data loading period in which up to 528 bytes(X8 device) or 264 words(X16 device) of data may be loaded into the page register, followed by a non-volatile programming period where the loaded data is programmed into the appropriate cell. About the pointer operation, please refer to the attached technical notes.

The serial data loading period begins by inputting the Serial Data Input command(80h), followed by the three cycle address input and then serial data loading. The words other than those to be programmed do not need to be loaded. The Page Program confirm command(10h) initiates the programming process. Writing 10h alone without previously entering the serial data will not initiate the programming process. The internal write controller automatically executes the algorithms and timings necessary for program and verify, thereby freeing the system controller for other tasks. Once the program process starts, the Read Status Register command may be entered, with RE and CE low, to read the status register. The system controller can detect the completion of a program cycle by monitoring the R/B output, or the Status bit(I/O 6) of the Status Register. Only the Read Status command and Reset command are valid while programming is in progress. When the Page Program is complete, the Write Status Bit(I/O 0) may be checked(Figure 9). The internal write verify detects only errors for "1"s that are not successfully programmed to "0"s. The command register remains in Read Status command mode until another valid command is written to the command register.

Figure 9. Program Operation

## BLOCK ERASE

The Erase operation is done on a block basis. Block address loading is accomplished in two cycles initiated by an Erase Setup command(60h). Only address A<sub>14</sub> to A<sub>23</sub> is valid while A<sub>9</sub> to A<sub>13</sub> is ignored. The Erase Confirm command(D0h) following the block address loading initiates the internal erasing process. This two-step sequence of setup followed by execution command ensures that memory contents are not accidentally erased due to external noise conditions.

At the rising edge of WE after the erase confirm command input, the internal write controller handles erase and erase-verify. When the erase operation is completed, the Write Status Bit(I/O 0) may be checked. Figure 10 details the sequence.

Figure 10. Block Erase Operation

## READ STATUS

The device contains a Status Register which may be read to find out whether program or erase operation is completed, and whether the program or erase operation is completed successfully. After writing 70h command to the command register, a read cycle outputs the content of the Status Register to the I/O pins on the falling edge of CE or RE, whichever occurs last. This two line control allows the system to poll the progress of each device in multiple memory connections even when R/B pins are common-wired. RE or CE does not need to be toggled for updated status. Refer to table 2 for specific Status Register definitions. The command register remains in Status Read mode until further commands are issued to it. Therefore, if the status register is read during a random read cycle, a read command(00h or 50h) should be given before sequential page read cycle.

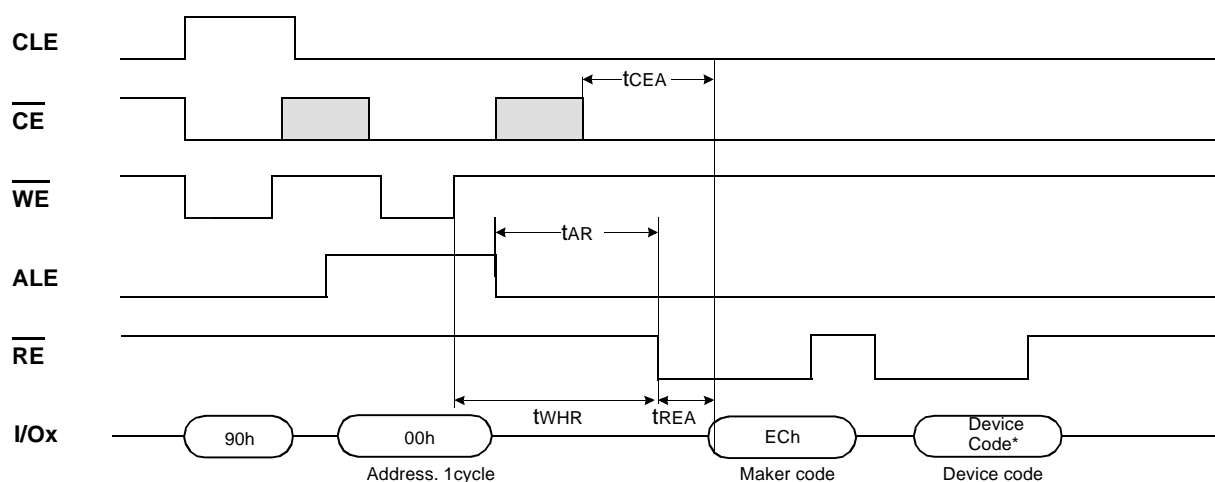

Table2. Read Status Register Definition

I/O #	Status	Definition
I/O 0	Program / Erase	"0" : Successful Program / Erase
		"1" : Error in Program / Erase
I/O 1	Reserved for Future Use	"0"
I/O 2		"0"
I/O 3		"0"
I/O 4		"0"
I/O 5		"0"
I/O 6	Device Operation	"0" : Busy "1" : Ready
I/O 7	Write Protect	"0" : Protected "1" : Not Protected
I/O 8~15	Not use	Dont care

## READ ID

The device contains a product identification mode, initiated by writing 90h to the command register, followed by an address input of 00h. Two read cycles sequentially output the manufacture code(ECh), and the device code respectively. The command register remains in Read ID mode until further commands are issued to it. Figure 11 shows the operation sequence.

Figure 11. Read ID Operation

Device	Device Code*
K9F2808Q0C	33h
K9F2808U0C	73h
K9F2816Q0C	43h
K9F2816U0C	53h

## RESET

The device offers a reset feature, executed by writing FFh to the command register. When the device is in Busy state during random read, program or erase mode, the reset operation will abort these operations. The contents of memory cells being altered are no longer valid, as the data will be partially programmed or erased. The command register is cleared to wait for the next command, and the Status Register is cleared to value C0h when  $\overline{WP}$  is high. Refer to table 3 for device status after reset operation. If the device is already in reset state a new reset command will not be accepted by the command register. The R/B pin transitions to low for  $t_{RST}$  after the Reset command is written. Refer to Figure 12 below.

Figure 12. RESET Operation

Table3. Device Status

	After Power-up	After Reset
Operation Mode	Read 1	Waiting for next command

## READY/BUSY

The device has a  $\overline{R/B}$  output that provides a hardware method of indicating the completion of a page program, erase and random read completion. The  $\overline{R/B}$  pin is normally high but transitions to low after program or erase command is written to the command register or random read is started after address loading. It returns to high when the internal controller has finished the operation. The pin is an open-drain driver thereby allowing two or more  $\overline{R/B}$  outputs to be Or-tied. Because pull-up resistor value is related to  $t_r(\overline{R/B})$  and current drain during busy( $i_{busy}$ ), an appropriate value can be obtained with the following reference chart(Fig 13). Its value can be determined by the following guidance.

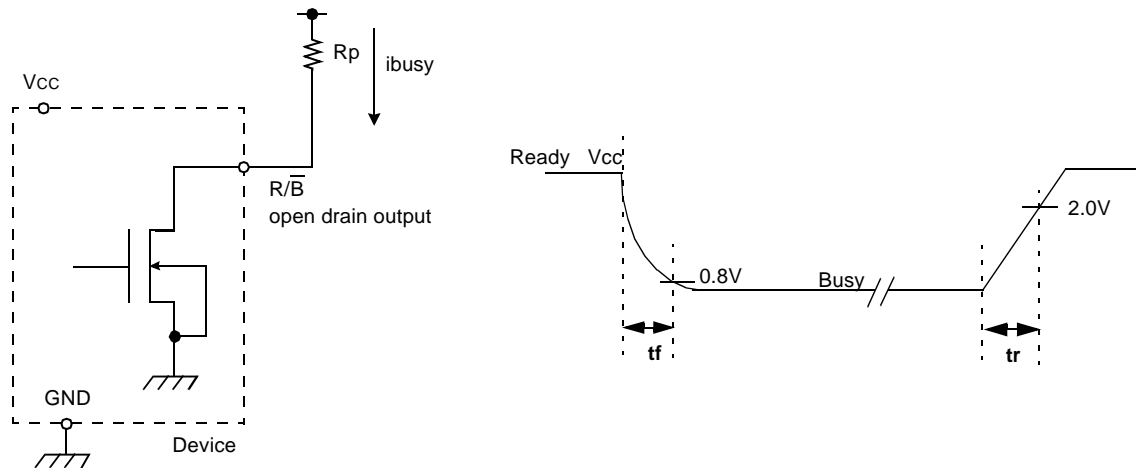

Fig 13  $R_p$  vs  $t_r, t_f$  &  $R_p$  vs  $i_{busy}$

@  $V_{cc} = 3.3V$ ,  $T_a = 25^\circ C$ ,  $C_L = 100pF$

### $R_p$ value guidance

$$R_{p(\min, 1.8V \text{ part})} = \frac{V_{cc(\max.)} - V_{OL(\max.)}}{I_{OL} + \sum I_L} = \frac{1.85V}{3mA + \sum I_L}$$

$$R_{p(\min, 3.3V \text{ part})} = \frac{V_{cc(\max.)} - V_{OL(\max.)}}{I_{OL} + \sum I_L} = \frac{3.2V}{8mA + \sum I_L}$$

where  $I_L$  is the sum of the input currents of all devices tied to the  $\overline{R/B}$  pin.

$R_{p(\max)}$  is determined by maximum permissible limit of  $t_r$

### Data Protection & Powerup sequence

The device is designed to offer protection from any involuntary program/erase during power-transitions. An internal voltage detector disables all functions whenever  $V_{CC}$  is below about 1.3V.  $\overline{WP}$  pin provides hardware protection and is recommended to be kept at  $V_{IL}$  during power-up and power-down and recovery time of minimum  $10\mu s$  is required before internal circuit gets ready for any command sequences as shown in Figure 14. The two step command sequence for program/erase provides additional software protection.

Figure 14. AC Waveforms for Power Transition
