

Secondary Side Synchronous Post Regulator

July 2002

FEATURES

- Generates a Regulated Auxiliary Output in Isolated DC/DC Converters
- 0.8V $\pm 1.5\%$ Accurate Voltage Reference
- Dual N-Channel MOSFET Synchronous Drivers
- High Switching Frequency: Up to 500kHz
- Programmable Current Limit Protection
- Programmable Soft-Start
- Automatic Frequency Synchronization
- Small 16-Pin Thermally Enhanced TSSOP Package

APPLICATIONS

- 48V Isolated DC/DC Converters
- Multiple Output Supplies
- Offline Converters

DESCRIPTION

The LT[®]3710 is a high efficiency step-down switching regulator intended for auxiliary outputs in single secondary winding, multiple output power supplies.

The LT3710 drives dual synchronous N-channel MOSFETs and achieves high efficiency. With leading edge modulation, it operates well with either primary side peak current or voltage mode control. It is synchronized to the falling edge of the transformer secondary winding and can be used in both single-ended and double-ended isolated power converter topologies. A high speed operational amplifier is incorporated to achieve optimum compensation and fast transient response. A user selectable discontinuous conduction mode improves light load efficiency.

The LT3710 is available in a thermally enhanced TSSOP-16 exposed pad power package.

LT, LTC and LT are registered trademarks of Linear Technology Corporation.

3710 G02

3710 G03

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS

BOOST (Pin 1): Topside (Boosted) Driver Supply. This pin is used to bootstrap and supply the topside power switch gate drive circuitry. In normal operation V_{BOOST} is powered from the internally generated 8V GBIAS, $V_{\text{BOOST}} = V_{\text{SW}} + 8.2\text{V}$ when TGATE is on.

TGATE (Pin 2): Topside (Boosted) N-Channel MOSFET Driver. When TGATE is on, the voltage is equal to $V_{\text{SW}} + 6\text{V}$.

SW (Pin 3): Switch Node Connection to Inductor.

CSET (Pin 4): Oscillator Timing Pin. The capacitor on this pin sets the PWM switching frequency.

SYNC (Pin 5): Synchronization Input. This pin should be connected to the secondary side output of the power transformer with a series resistor. A filtering capacitor of 10pF is recommended.

ILCOMP (Pin 6): Current Limit Amplifier Compensation Node. At current limit, CA1 pulls down on this pin to regulate the output current.

SS (Pin 7): Soft-Start. A capacitor on this pin sets the output ramp up rate. The typical time for SS to reach the programmed level is $(C \cdot 0.8\text{V})/10\mu\text{A}$.

V_{FB} (Pin 8): Voltage Amplifier Inverting Input. A resistor divider to this pin sets the output voltage. Nominal voltage at this pin is 0.8V.

BGS (Pin 9): Bottom Gate Switching Control. CA2 monitors the inductor current and prohibits BGATE from turning on when the inductor current is low (below 8mV across the current sense resistor RS1) to allow discontinuous mode operation. Grounding this pin disables comparator CA2.

VA_{OUT} (Pin 10): Voltage Amplifier Output.

CL⁺ (Pin 11): Current Limit Amplifier Positive Input. The threshold is set at 70mV.

CL⁻ (Pin 12): Current Limit Amplifier Negative Input. When used, CL⁻ is connected to the output capacitor side of the current + sense resistor and CL⁺ is connected to the inductor side of the current sense resistor.

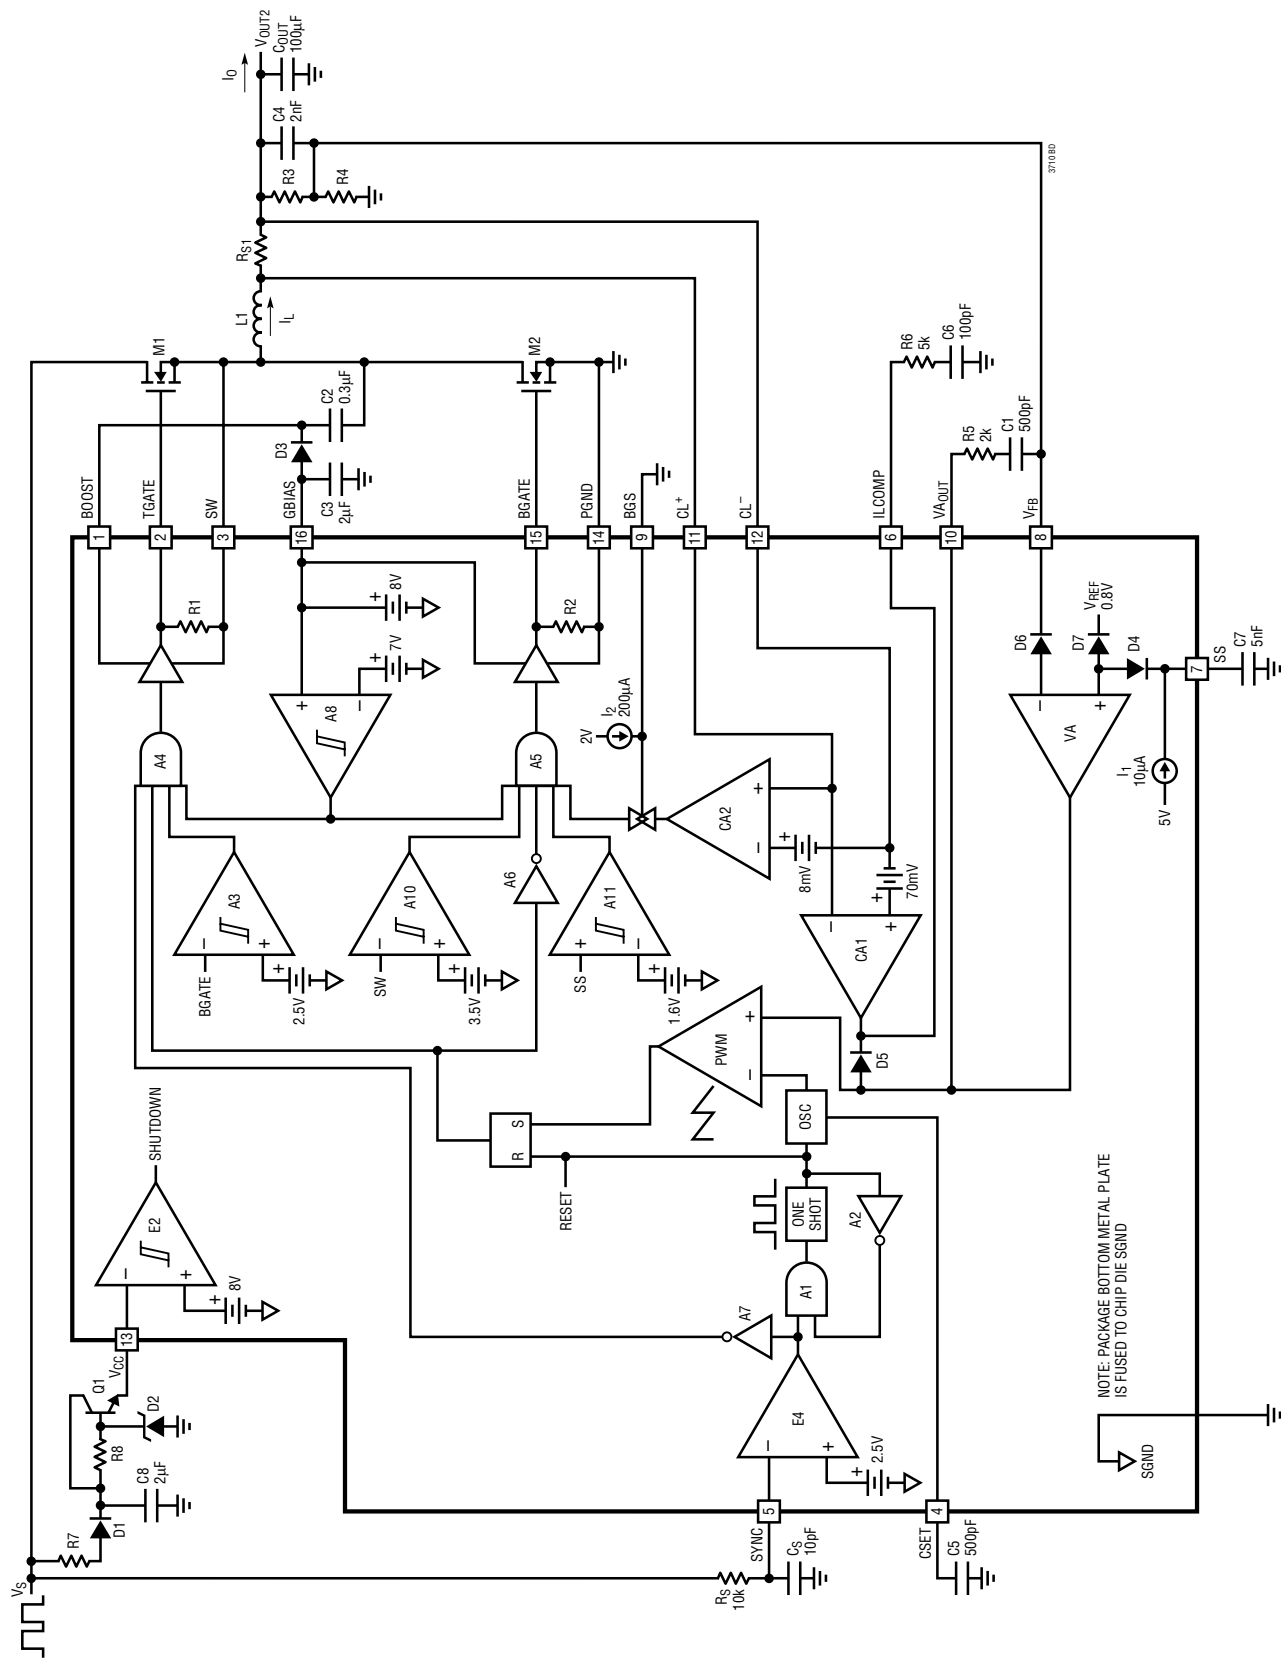

V_{CC} (Pin 13): Supply of the IC. For proper bypassing, a low ESR capacitor is required.

PGND (Pin 14): Ground of the Bottom Side N-Channel MOSFET Driver.

BGATE (Pin 15): Bottom Side N-Channel MOSFET Driver.

GBIAS (Pin 16): 8V Regulator Output for Bootstrapping V_{BOOST} . A bypass capacitor of at least 2μF is needed.

BLOCK DIAGRAM

OPERATION

To generate isolated multiple outputs, most systems use either multiple secondary windings or cascade regulators for each additional output. Multiple secondary windings sacrifice regulation of the auxiliary outputs. Cascaded regulators require a larger inductor for the main output, because all of the power is processed in series.

By generating the auxiliary output(s) from the secondary winding of the main output, the LT3710 allows for parallel processing of the output power. This minimizes the main output inductor size and directly regulates the auxiliary output. With synchronous rectification, the system efficiency is greatly improved.

Referring to the Block Diagram, the LT3710 basic functions include a voltage amplifier, VA, to regulate the output voltage to within typically 1.5%, a voltage mode PWM with trailing edge synchronization and leading edge modulation, a current limit amplifier, CA1, and high speed synchronous switch drivers.

During normal operation (see Figure 2), a switching cycle begins at the falling edge of the transformer secondary voltage V_S . The internal oscillator is reset, turning off the top MOSFET M1 and turning on the bottom MOSFET M2. During this portion of the cycle, the inductor current is discharged by the output voltage V_{OUT2} . The transformer secondary voltage V_S will go high during this portion of the cycle. Since M1 is off, the switch node voltage V_{SW} remains zero. The inductor current continues to be discharged by the output voltage V_{OUT2} . This condition lasts

until the ramp signal intersects the feedback error amplifier output V_{AOUT} . The top MOSFET M1 turns on, pulling the switch node voltage to V_S . The inductor current of the LT3710 circuit is then charged by $V_S - V_{OUT2}$. The effective on time of this buck circuit ends when the secondary voltage becomes zero. The next cycle repeats.

The ideal equation for duty cycle of the LT3710 is:

$$D2 = V_{OUT2}/V_{SP}$$

where V_{OUT2} is the auxiliary output voltage, V_{SP} is the amplitude of the secondary voltage and $D2$ is the duty cycle of the switching node voltage V_{SW} , as defined in Figure 2.

Figure 2. Leading Edge Modulation, Trailing Edge Synchronization

APPLICATIONS INFORMATION

Synchronization and Oscillation Frequency Setting

The switching is synchronized to the secondary winding falling edge and the synchronization threshold is typically 2.5V. The synchronization falling edge triggers an internal inverted ramp (see Figure 2) and starts a new switching cycle for the leading edge voltage mode PWM. The reason for using leading edge modulation is to keep the transformer primary side peak current sensing undisturbed.

For proper synchronization, the oscillator frequency should be set lower than the system switching frequency with tolerances taken into account.

$$f_{OSC} < (f_{SL} \cdot 0.8)$$

f_{SL} is the low limit of the system switching frequency and 0.8 is the tolerance of f_{OSC} .

For example, a system of 200kHz with 15% tolerance, then $f_{SL} = 200k \cdot 85\% = 170kHz$; and $f_{OSC} < (170k \cdot 0.8)$, f_{OSC} should be set below 136kHz.

Once f_{OSC} is determined, CSET can be calculated by $CSET = (107250pf/f_{OSC(kHz)}) - 50pF$.

For $f_{OSC} = 100kHz$, $CSET = 1022.5pF$.

APPLICATIONS INFORMATION

Output N-Channel MOSFET Drivers

The LT3710 employs high speed N-channel MOSFET synchronous drivers to achieve high system efficiency. GBIAS is the 8V regulator output to bias and supply the drivers and should be properly bypassed with a low ESR capacitor to ground plane. A Schottky catch diode is required on the switch node.

Light Load Operation

If the BGS pin is grounded, the LT3710 stays in continuous mode independent of load condition except in soft-start operation (see Soft-Start section). If the BGS pin is left open, under light load and V_{RS1} drops below 8mV, BGATE will be turned off (see comparator CA2 of Block Diagram) and the LT3710 goes into discontinuous mode operation.

Current Limit

Current limit is set by the 70mV threshold across CL^+ and CL^- , the inputs of the amplifier CA1. By connecting an external resistor $RS1$ (see Block Diagram), the current limit is set for $70mV/R_{S1}$. $R6$ and $C6$ stabilize the current limit loop. If current limit is not used, both CL^+ and CL^- should be grounded and the BGS pin should also be grounded to disable comparator CA2.

Soft-Start and Shutdown

During soft-start, V_{SS} is the reference voltage that controls the output voltage and the output ramps up following V_{SS} . The effective range of V_{SS} is from 0V to V_{REF} . The typical time for the output to reach the programmed level is $(C \cdot 0.8V)/10\mu A$.

During start up, BGATE will stay off until V_{SS} gets up to 1.6V. This prevents the bottom MOSFET from turning on if the output is precharged.

To shut down the LT3710, the SS pin should be pulled below 50mV by a VN2222 type N-channel transistor. Note that during shutdown BGATE will be locked off when V_{SS} drops below 0.6V. This prevents the bottom MOSFET from discharging the output, which would cause the output to undershoot below ground.

Layout Considerations

For maximum efficiency, the switching rise and fall times are less than 20ns. To prevent radiation, the power MOSFETs, SW pin and input bypass capacitor leads should be kept as short as possible. A ground plane should be used under the switching circuitry to prevent interplane coupling and to act as a thermal spreading path. Note that the bottom metal of the package is the heat sink, as well as the IC signal ground, and must be soldered to the ground plane.

Output Voltage Programming

The feedback reference voltage is 0.8V. The output voltage can be easily programmed by the resistor divider, $R3$ and $R4$, as shown in the Block Diagram.

$$V_{OUT2} = 0.8 \cdot \left(1 + \frac{R3}{R4}\right)$$

Filtering on the SYNC Input

It is necessary to add RC filtering on the SYNC input of the LT3710 to eliminate the negative glitch at the turn on of the top MOSFET. When the top MOSFET M1 turns on, the transformer secondary current instantly changes from the original first output inductor current to the sum of two output inductor currents. The high di/dt on the transformer leakage inductance causes the transformer secondary voltage V_S to drop for a short interval. If the leakage inductance is large enough, the V_S dip will be lower than the synchronization threshold (about 2.5V), falsely triggering the synchronization. The top MOSFET is turned off immediately. As a result, the output voltage will not be regulated properly.

A filter circuit is needed to ensure proper operation. A small RC filter with $R_S = 10k$ and $C_S = 10pF$ are typical.

APPLICATIONS INFORMATION

Output Inductor Selection

The key parameters for choosing the inductor include inductance, RMS and saturation current ratings and DCR. The inductance must be selected to achieve a reasonable value of ripple current, which is determined by:

$$\Delta I_L = \frac{V_{OUT2} \cdot (1 - D2)}{f \cdot L}$$

Typically, the inductor ripple current is designed to be 20% to 40% of the maximum output current.

The RMS current rating must be high enough to deliver the maximum output current. A sufficient saturation current rating should prevent the inductor core from saturating. These two current ratings can be determined by:

$$I_{RMS} \geq \sqrt{I_0^2 + \frac{\Delta I_{LMAX}^2}{12}}$$

$$I_{SAT} \geq I_0 + \frac{\Delta I_{LMAX}}{2}$$

where I_0 is the maximum output current and ΔI_{LMAX} is the maximum peak-to-peak inductor ripple current.

To optimize the efficiency, we usually choose the inductor with the minimum DCR if the inductance and current ratings are the same.

Power MOSFET Selection

The LT3710 drives two external N-channel MOSFETs to deliver high currents at high efficiency. The gate drive voltage is typically 6.5V. The key parameters for choosing MOSFETs include drain to source voltage rating V_{DS} and $R_{DS(ON)}$ at 6.5V gate drive. Note that the transformer secondary voltage waveform will overshoot at its rising edge due to the ringing between transformer leakage inductance and parasitic capacitance. The V_{DS} of both top and bottom MOSFETs must be sufficiently higher than the maximum overshoot. It is recommended that an RC snubber or a voltage clamping circuitry be placed across the transformer secondary winding to limit the V_S overshoot.

The $R_{DS(ON)}$ of the MOSFETs should be selected to deliver the required current at the desired efficiency as well as to meet the thermal requirement of the MOSFET package. The conduction power losses of the MOSFETs are:

$$P_{M1} \cong I_0^2 \cdot R_{DS(ON)M1} \cdot D2$$

$$P_{M2} \cong I_0^2 \cdot R_{DS(ON)M2} \cdot (1 - D2)$$

where I_0 is the maximum output current of LT3710 circuit, $R_{DS(ON)M1}$ and $R_{DS(ON)M2}$ are the on-resistance for the top and bottom MOSFETs, respectively. The $R_{DS(ON)}$ must be determined with 6.5V gate drive and the expected operating temperature.

A good number of high performance power MOSFET selections are available from Siliconix, International Rectifier and Fairchild. If the V_{DS} and $R_{DS(ON)}$ ratings are the same, the MOSFETs with the lowest gate charge Q_G should be chosen to minimize the power loss associated with the MOSFET gate drives, the switching transitions and the controller bias supply.

Output Capacitor Selection

The selection of the output capacitor is determined by the output ripple and load transient requirements. In low output voltage applications, always choose capacitors with low ESR. The output ripple voltage is approximated by:

$$\Delta V_{OUT} \approx \Delta I_L \left(ESR + \frac{1}{8fC_{OUT}} \right)$$

where ΔI_L is the inductor peak-to-peak ripple current.

A partial list of low ESR high performance capacitor types includes SP capacitors from Panasonic and Cornell Dubilier, POSCAPs and OS-CON capacitors from Sanyo, T510 and T520 surface mount capacitors from Kemet.

Design Example

Figure 3 shows an application example for the LT3710. It is a dual output, high efficiency, isolated DC/DC power supply with 36V to 72V input, 3.3V/10A and 1.8V/10A outputs. The basic power stage topology is a 2-transistor forward converter with synchronous rectification. The
