

PDC4UV6414C-(102/103)T-S **32MByte (4M x 64) CMOS, PC/100** **Synchronous DRAM Module**

General Description

The PDC4UV6414C-(102/103)T-S is a high performance, 32-megabyte synchronous, dynamic RAM module organized as 4M words by 64 bits, in a 168-pin, dual-in-line memory module (DIMM) package.

The module utilizes four Fujitsu MB81F641642C-(102/103)FN CMOS 4Mx16 synchronous dynamic RAMs in surface mount package (TSOP) on an epoxy laminated substrate. Each device is accompanied by a decoupling capacitor for improved noise immunity.

A 256 Byte Serial EEPROM contains the module configuration information.

Features

- High Density 32MByte
- Cycle Time: 10ns
- Low Power: Active 3.5W
- LVTTTL-compatible inputs and outputs
- Separate power and ground planes to improve noise immunity
- Single power supply of 3.3V±0.3V
- Height: 1.375 inch

†CL = CAS* Latency

- Notes:
- I_{CC} depends on the output termination or load conditions, clock cycle rate, and signal clocking rate;
The specified values are obtained with the output open and no termination register.
 - An initial pause (DESL or NOP) of 200 μs is required after power-up followed by a minimum of eight Auto-refresh cycles.

$\overline{\text{CAS}}$ to $\overline{\text{CAS}}$ Delay (min)		l_{CCD}	cycle	1	1	
$\overline{\text{CAS}}$ Bank Delay (min)		l_{CBD}	cycle	1	1	

- Notes:
- l_{CC} depends on the output termination or load conditions, clock cycle rate, and signal clocking rate; The specified values are obtained with the output open and no termination register.
 - An initial pause (DESL or NOP) of 200 μs is required after power-up followed by a minimum of eight Auto-refresh cycles.
 - AC characteristics assume $t_{\text{T}} = 1 \text{ ns}$ and 50 pF of capacitive load.
 - 1.4 V is the reference level for measuring timing of input signals. Transition times are measured between V_{IH} (min) and V_{IL} (max).
 - Assumes t_{RCD} is satisfied.
 - t_{AC} also specifies the access time at burst mode.
 - Specified where output buffer is no longer driven.
 - Actual clock count of t_{RC} (l_{RC}) will be sum of clock count of t_{RAS} (l_{RAS}) and t_{RP} (l_{RP}).
 - Operation within the t_{RCD} (min) ensures that access time is determined by t_{RCD} (min) + t_{AC} (max); If t_{RCD} is greater than the specified t_{RCD} (min), access time is determined by t_{AC} .
 - All base values are measured from the clock edge at the command input to the clock edge for the next command input. All clock counts are calculated by a simple formula: clock count equals base value divided by clock period (round off a whole number).

Note: AC characteristics are measured in this condition. This load circuits are not applicable for V_{OH} and V_{OL} .
