

3-Terminal Medium Current Negative Voltage Regulators

The PJ79M00 Series negative voltage regulators are identical to the popular PJ7900 Series devices, except that they are specified for only half the output current. Like the PJ7900 devices, the PJ79M00 Terminal regulators are intended for local, on-card voltage regulation.

Internal current limiting, thermal shutdown circuitry and safe-area compensation for the internal pass transistor combine to make these devices remarkably rugged under most operating conditions. Maximum output current, with adequate heat sinking is 500mA

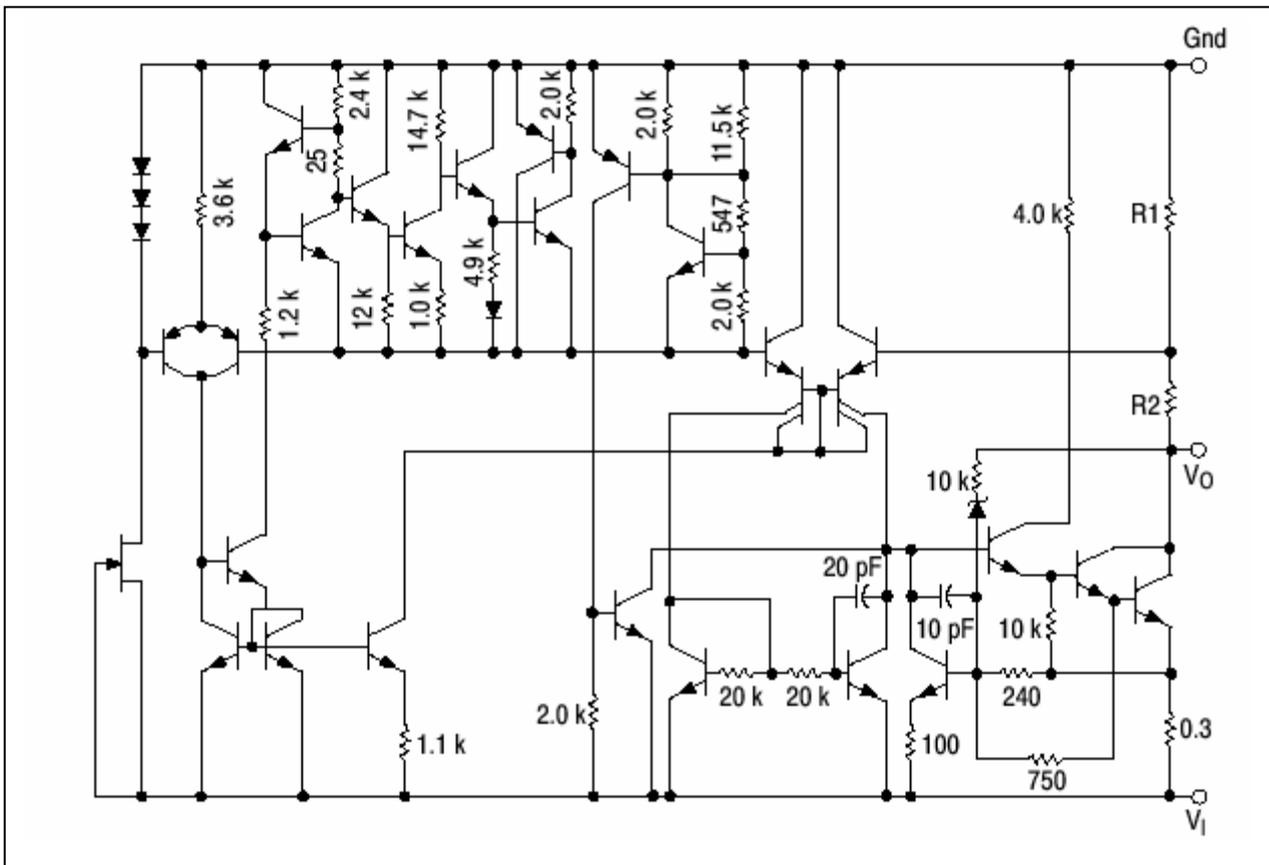

FEATURES

- No External Components Required
- Internal Thermal Overload Protection
- Internal Short Circuit Current Limiting
- Output Transistor Safe-Area Compensation
- Output Voltage Offered in 4% Tolerance

DEFINITIONS

Line-Regulation-The change in ooutput voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature in not significantly affected.

Load-Regulation-The change in output voltage for a change in load current at constant chip temperature.

Maximum Power dissipation-The maximum total device dissipation for which the regulator will operate within specifications.

Input Bias Current-That part of the input current that is not delivered to the load.

Output Noise Voltage-The rms AC voltage at the output,with constant load and no input ripple,measured over a specified frequency range.

Long Term Stability-Output voltage stability under accelerated life test conditions with the maximum rated voltage listed in the devices' electrical characteristics and maximum power dissipation.

APPLICATIONS INFORMATION

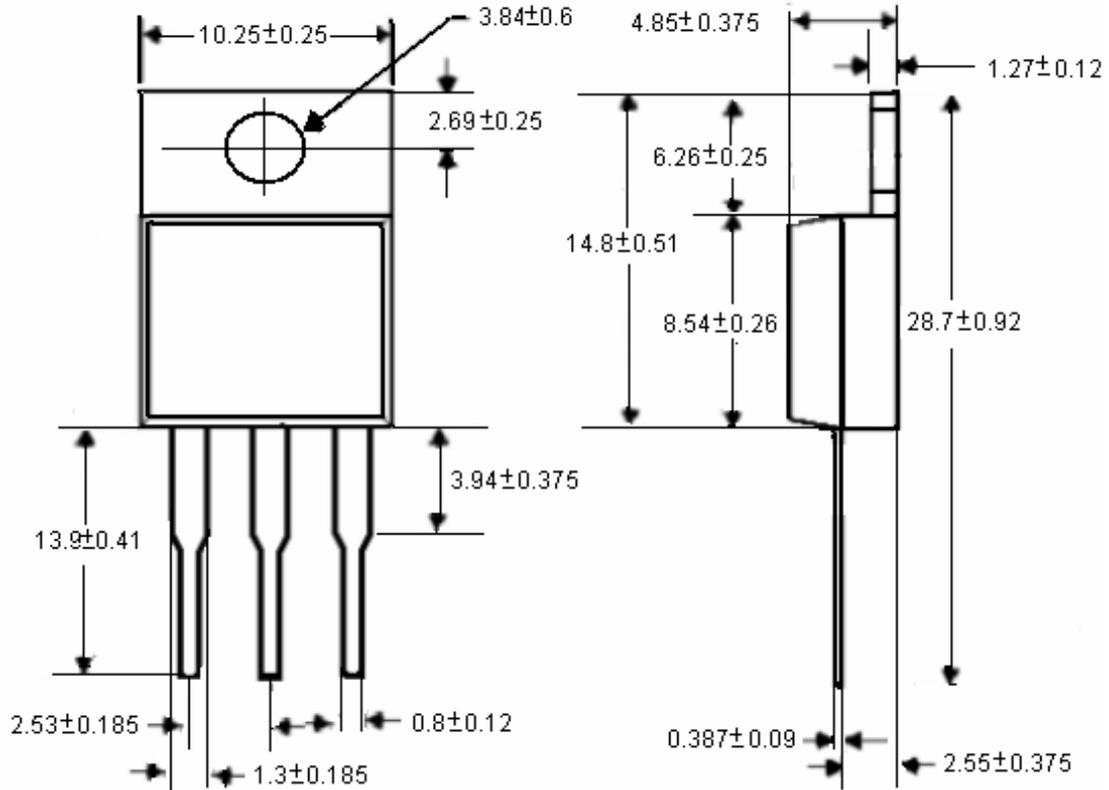

Design Considerations

The PJ79Mxx Series of fixed voltage regulators are designed with Thermal Overload Protection that shuts down the circuit when subjected to an excessive power overload condition, Internal Short Circuit Protection that limits the maximum current the circuit will pass, and Output Transistor Safe-Area Compensation that reduces the output short circuit current as the voltage across the pass transistor is increased.

In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with a capacitor if the regulator is connected to the power supply filter with long wire lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high frequency characteristics to insure stable operation under all load conditions. A 0.33 mF or larger tantalum, Mylar, or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulator's input terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.
