

### Typical Applications

- Wireless Meter Reading
- TDD Systems
- 433/868/915MHz ISM Band Systems
- Wireless Data Transceiver
- Wireless Security Systems
- Battery Powered Portable Devices

### Product Description

The RF2925 is a monolithic integrated circuit intended for use as a low cost FM transceiver. The device is provided in 48-lead plastic LQFP packaging and is designed to provide a fully functional FM transceiver. The chip is intended for linear (AM, FM) or digital (ASK, FSK, OOK) applications in the North American 915MHz ISM band and European 433MHz and 868MHz ISM bands. The integrated VCO, dual modulus/dual divide (128/129 or 64/65) prescaler, and reference oscillators require only the addition of an external crystal to provide a complete phase-locked oscillator. The RF2925 differs from the RF2905 in that both reference oscillators are always on when the PLL is enabled which decreases start-up time when switching between transmit and receive oscillators.

### Optimum Technology Matching® Applied

- ☒ Si BJT    ☐ GaAs HBT    ☐ GaAs MESFET  
☐ Si Bi-CMOS    ☐ SiGe HBT    ☐ Si CMOS

### Package Style: LQFP-48

### Features

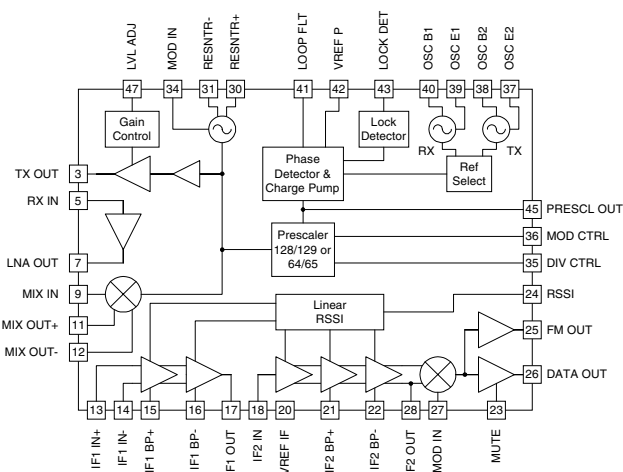

- Fully Monolithic Integrated Transceiver
- Fast Switching from Transmit to Receive
- Narrow Band and Wide Band FM/FSK
- 300MHz to 1000MHz Frequency Range
- 2.7V to 5.0V Supply Voltage
- 10mW Output Power at 433MHz

### Ordering Information

RF2925	433/868/915MHz FM/FSK/ASK/OOK Transceiver
RF2925 PCBA-L	Fully Assembled Evaluation Board (433MHz)
RF2925 PCBA-M	Fully Assembled Evaluation Board (868MHz)
RF2925 PCBA-H	Fully Assembled Evaluation Board (915MHz)

Pin	Function	Description	Interface Schematic
1	<b>RX ENABL</b>	Enable pin for the receiver circuits. RX ENABL > 2.0V powers up all receiver functions. RX ENABL < 1.0V turns off all receiver functions except the PLL functions and the RF mixer. When RX ENABL is high the receive LO frequency is set by reference oscillator 1.	
2	<b>TX ENABL</b>	Enables the transmitter circuits. TX ENABL > 2.0V powers up all transmitter functions. TX ENABL < 1.0V turns off all transmitter functions except the PLL functions. When TX ENABL is high the transmit frequency is set by reference oscillator 2.	
3	<b>TX OUT</b>	RF output pin for the transmitter electronics. TX OUT output impedance is a low impedance (see output impedance plot) when the transmitter is enabled. TX OUT is a high impedance when the transmitter is disabled.	
4	<b>GND2</b>	Ground connection for the 40dB IF limiting amplifier and Tx PA functions. Keep traces physically short and connect immediately to ground plane for best performance.	
5	<b>RX IN</b>	RF input pin for the receiver electronics. RX IN input impedance is a low impedance (see input impedance plot) when the transmitter is enabled. RX IN is a high impedance when the receiver is disabled.	
6	<b>GND1</b>	Ground connection for RF receiver functions. Keep traces physically short and connect immediately to ground plane for best performance.	
7	<b>LNA OUT</b>	Output pin for the receiver RF low noise amplifier. This pin is an open collector output and requires an external pull up coil to provide bias and tune the LNA output.	
8	<b>GND3</b>	Same as pin 4.	
9	<b>MIX IN</b>	RF input to the RF Mixer. An LC matching network between LNA OUT and MIX IN can be used to connect the LNA output to the RF mixer input in applications where an image filter is not needed or desired.	
10	<b>GND5</b>	GND5 is the ground connection shared by the input stage of the transmit power amplifier and the receiver RF mixer.	
11	<b>MIX OUT+</b>	Complementary (with respect to pin 12) IF output from the RF mixer. Interfaces directly to 10.7MHz ceramic IF filters as shown in the application schematic. A pull-up inductor and series matching capacitor should be used to present a 330Ω termination impedance to the ceramic filter. Alternately, an IF tank can be used to tailor the IF frequency and bandwidth to meet the needs of a given application.	
12	<b>MIX OUT-</b>	IF output from the RF mixer. For a balanced mixer output, pull-up inductors from pin 11 and 12 to VCC and a capacitor between the pins should be used. The sum of the total pull-up inductance should be used to resonate the capacitor between pins 11 and 12. DC blocking capacitors of 10nF can then be used to connect the balanced output to IF1 IN+ (pin 13) and IF1 IN- (pin 14).	See pin 11.

Pin	Function	Description	Interface Schematic
13	IF1 IN+	Balanced IF input to the 40dB limiting amplifier strip. A 10nF DC blocking capacitor is required on this input.	
14	IF1 IN-	Functionally the same as pin 13 except inverting node amplifier input. In single-ended applications, this input should be bypassed directly to ground through a 10nF capacitor.	See pin 13.
15	IF1 BP+	DC feedback node for the 40dB limiting amplifier strip. A 10nF bypass capacitor from this pin to ground is required.	See pin 13.
16	IF1 BP-	Same as pin 15.	See pin 13.
17	IF1 OUT	IF output from the 40dB limiting amplifier. The IF1 OUT output presents a nominal 330Ω output resistance and interfaces directly to 10.7MHz ceramic filters.	
18	IF2 IN	Balanced IF input to the 60dB limiting amplifier strip. A 10nF DC blocking capacitor is required on this input. The IF2 IN input presents a nominal 330Ω input resistance and interfaces directly to 10.7MHz ceramic filters.	
19	GND6	Ground connection for 60dB IF limiting amplifier. Keep traces physically short and connect immediately to ground plane for best performance.	
20	VREF IF	DC voltage reference for the IF limiting amplifiers. A 10nF capacitor from this pin to ground is required.	
21	IF2 BP+	DC feedback node for the 60dB limiting amplifier strip. A 10nF bypass capacitor from this pin to ground is required.	See pin 18.
22	IF2 BP-	Same as pin 21.	See pin 18.
23	MUTE	This pin is used to mute the data output (DATA OUT). MUTE>2.0V turns the DATA OUT signal on. MUTE<1.0V turns the DATA OUT signal off. The MUTE signal should be logic low in the Sleep Mode.	
24	RSSI	A DC voltage proportional to the received signal strength is output from this pin. The output voltage range is 0.5V to 2.5V and increases with increasing signal strength.	
25	FM OUT	Linear output from the FM demodulator. This pin is used in analog applications when signal fidelity is important. This output is inverted for low side injection of the LO and normal for high side injection.	
26	DATA OUT	Demodulated data output from the demodulator. Output levels on this are TTL/CMOS compatible. The magnitude of the load impedance is intended to be 1MΩ or greater. When using a RF2905 transmitter and receiver back to back, a data inversion will occur, when the LO is low side injected. A high side injection will add an inversion of the Rx data.	

Pin	Function	Description	Interface Schematic
27	DEMOD IN	This pin is the input to the FM demodulator. This pin is NOT AC coupled. Therefore, a DC blocking capacitor is required on this pin to avoid shorting the demodulator input with the LC tank. A ceramic discriminator or DC blocked LC tank resonant at the IF should be connected to this pin.	
28	IF2 OUT	Balanced IF output from the 60dB limiting amplifier strip. This pin is intended to be connected to pin 27 through a 5pF capacitor and an FM discriminator circuit.	
29	VCC6	This pin is used to supply DC bias to the 60dB IF limiting amplifier. An IF bypass capacitor should be connected directly to this pin and returned to ground. A 10nF capacitor is recommended for 10.7MHz IF applications.	
30	RESNTR+	This port is used to supply DC voltage to the VCO as well as to tune the center frequency of the VCO. Equal value inductors should be connected to this pin and pin 31 although a small imbalance can be used to tune in the proper frequency range.	
31	RESNTR-	See RESNTR+ description.	See pin 30.
32	VCC2	This pin is used to supply DC bias to the VCO, prescaler, and PLL. An RF bypass capacitor should be connected directly to this pin and returned to ground. A 22pF capacitor is recommended for 915MHz applications. A 68 pF capacitor is recommended for 433MHz applications.	
33	GND4	GND4 is the ground shared on chip by the VCO, prescaler, and PLL electronics.	
34	MOD IN	FM analog or digital modulation can be imparted to the VCO through this pin. The VCO varies in accordance to the voltage level presented to this pin. To set the deviation to a desired level, a voltage divider referenced to VCC is the recommended. This deviation is also dependent upon the overall capacitance of the external resonant circuit.	See pin 30.
35	DIV CTRL	This pin is used to select the desired prescaler divisor. A logic high (DIV CTRL > 2.0V) selects the 64/65 divisor. A logic low (DIV CTRL < 1.0V) selects the 128/129 divisor.	
36	MOD CTRL	This pin is used to select the prescaler modulus. A logic high (MOD CTRL > 2.0V) selects 64 or 128 for the prescaler divisor. A logic low (MOD CTRL < 1.0V) selects 65 or 129 for the prescaler divisor. Due to design timing constraints, the prescaler in the divide by 65 or 129 modes has a limited frequency range for accurate operation. These two modes are not recommended for use from 400MHz to 460MHz.	
37	OSC E2	Oscillator emitter. See pin 1 description.	See pin 38.
38	OSC B2	Oscillator base. The application schematic shows a typical Colpitts oscillator circuit. This pin may be driven by an external source. If so, it should be AC coupled using a capacitor. The level should be about 500mV <sub>PP</sub>	

Pin	Function	Description	Interface Schematic
39	OSC E1	Oscillator emitter. See pin 1 description.	See pin 40.
40	OSC B1	Oscillator base. The application schematic shows a typical Colpitts oscillator circuit. This pin may be driven by an external source. If so, it should be AC coupled using a capacitor. The level should be about 500mV <sub>PP</sub>	
41	LOOP FLT	Output of the charge pump, and input to the VCO control. An RC network from this pin to ground is used to establish the PLL bandwidth.	
42	VREF P	Bypass pin for the prescaler reference voltage. A 33nF capacitor to ground is needed to suppress reference spurs in the device. This value may be different for different PCB arrangements.	
43	LOCK DET	This pin provides an analog output indicating the lock status of the PLL. The amplitude of this signal is typically 200mV <sub>PP</sub> around a DC level of V <sub>CC</sub> -0.1V.	
44	VCC1	This pin is used to supply DC bias to the receiver RF electronics. An RF bypass capacitor should be connected directly to this pin and returned to ground. A 22pF capacitor is recommended for 915MHz applications. A 68pF capacitor is recommended for 433MHz applications.	
45	PRESCL OUT	Dual-modulus/Dual-divide prescaler output. The output can be interfaced to an external PLL IC for additional flexibility in frequency programming.	
46	VCC3	This pin is used to supply DC bias to the transmitter PA. An RF bypass capacitor should be connected directly to this pin and returned to ground. A 22pF capacitor is recommended for 915MHz applications. A 68pF capacitor is recommended for 433MHz applications.	
47	LVL ADJ	This pin is used to vary the transmitter output power. An output level adjustment range greater than 12dB is provided through analog voltage control of this pin. DC current of the transmitter power amp is also reduced with output power. This pin MUST be low when the transmitter is disabled.	
48	PLL ENABL	This pin is used to power up or down the VCO and PLL. A logic high (PLL ENABL > 2.0V) powers up the VCO and PLL electronics. A logic low (PLL ENABL < 1.0V) powers down the PLL and VCO.	

## RF2925 Theory of Operation and Application Information

The RF2925 is a part of a family of low-power RF transceiver IC's that was developed for wireless data communication devices operating in the European 433/868MHz ISM bands or 915MHz US ISM band. This IC has been implemented in a 15GHz silicon bipolar process technology that allows low-power transceiver operation in a variety of commercial wireless products.

In its basic form, the RF2925 can implement a two-way half duplex FSK transceiver with the addition of some crystals, filters, and passive components. There are two reference crystals that allow for the transmit carrier and the receiver LO to be independently generated with a common PLL and VCO. The receiver IF section is optimized to interface with low cost 10.7MHz ceramic filters but has a -3dB bandwidth of 25MHz and can still be used (with lower gain) at higher frequency with the other type of filters. The PA output and LNA input are available on separate pins and are designed to be connected together through a DC blocking capacitor. In the Transmit mode, the PA will have a 50 $\Omega$  impedance and the LNA will be a high impedance. In Receive mode, the LNA will have a 50 $\Omega$  interface and the PA will have a high impedance. This eliminates the need for a TX/RX switch and allows a single RF filter to be used in transmit and receive modes. Separate access to the PA and LNA allow the RF2925 to interface with external components such as higher power PA's, lower NF LNA's, upconverters, and downconverters for a variety of implementations.

### FM/FSK SYSTEMS

The MOD IN pin drives an internal varactor for modulating the VCO. This pin can be driven with a voltage level needed to generate the desired deviation. This voltage can be carried on a DC bias to select the desired slope (deviation/volt) for FM systems. Or, a resistor divider network referenced to Vcc or ground can divide down logic level signals to the appropriate level for a desired deviation in FSK systems.

On the receiver demod, two outputs are available, an analog FM output and a digital FSK output. The FM output is a buffered signal coming off of the quadrature demodulator. The digital output is generated by a data slicer that is DC coupled differentially to the demodulator. An on-chip 1.6MHz RC filter is provided at the demodulator output to filter the undesired 2xIF product. This balanced data slicer has a speed advantage over a conventional adaptive data slicer where a large capacitor is used to provide DC reference for bit decision. Since the balanced data slicer does not have to

charge a large capacitor, the RF2925 exhibits a very fast response time. For best operation of the on-chip data slicer, FM deviation needs to exceed the carrier frequency error anticipated between the receiver and transmitter with margin.

The data slicer itself is a transconductance amp and the DATA OUT pin is capable of driving rail to rail output only into a very high impedance and small capacitance. The amount of capacitance will determine the bandwidth of the DATA OUT. At a 3pF load, the bandwidth is in excess of 500kHz. The rail to rail output of the data slicer is also limited by the frequency deviation and bandwidth of the IF filters. With the 180kHz bandwidth filters on the eval boards, the rail to rail output is limited to less than 140kHz. Choosing the right IF bandwidth and deviation vs. data rate (mod index) is important in evaluating the applicability of the RF2925 for a given data rate.

While this type of data slicer is best for wideband deviation, it can also work for narrowband if care is taken to minimize frequency differences. By loading down the DATA OUT pin, the output will be limited to a small data signal on a DC carrier. With this signal, an external data slicer can be used to achieve higher data rates or improve performance in narrow deviations. Alternatively, an AFC loop can be added to correct for frequency errors with a few external components.

For FM or FSK modulation, an internal varactor is used to directly modulate the VCO with the baseband data. The primary consideration when directly modulating the VCO is the data rate verses PLL loop bandwidth. The PLL will track out the modulation to the extent of its loop bandwidth which distorts the modulating data. Therefore, the lower frequency components of the modulating data should be 5 to 10 times the loop bandwidth to minimize the distortion. The lower frequency components are generated by long strings of 1's or 0's in the data stream. By limiting the number of consecutive, same bits, the lower frequency component can be set. In addition, the data stream should be balanced to minimize distortion. Using a coding pattern such as Manchester is highly recommended to optimize system performance.

The PLL loop bandwidth is important in several other system parameters. For example, switching from transmit to receive requires the VCO to retune to another frequency. The switching speed is proportional to the loop bandwidth, the higher the loop bandwidth, the

faster the switching times. Phase noise of the VCO is another factor. Phase noise outside of the loop bandwidth is due to the noise of the VCO itself rather than the crystal reference. A design trade-off must be made here in selecting a PLL loop bandwidth with acceptable phase noise and switching characteristics and minimal distortion of the modulation data.

### AM/ASK SYSTEMS

The transmitter of the RF2925 has an output power level adjustment (LVL ADJ) that can be used to provide approximately 18dB of power control for amplitude modulation. The RSSI output of the receiver section can be used to recover the modulation. The RSSI output is from a current source and needs to have a resistor to convert to a voltage. A 51k $\Omega$  resistive load will produce an RSSI voltage of 0.7V to 2.5V, typically. A parallel capacitor is suggested to limit the bandwidth and filter noise. For ASK applications, the 18dB range of the LVL ADJ does not produce enough voltage swing in the RSSI for reliable communication. The On-Off keying (OOK) is suggested to provide reliable communications. To achieve this, both the LVL ADJ and TX ENABL need to be controlled together (please note that LVL ADJ cannot be left high when TX ENABL is low). This will provide a on/off ratio of >50dB. One unfortunate consequence of modulating this way is VCO pulling by the power amp. This results in a spurious output outside the desired transmit band as the PLL momentarily loses lock and reacquires. This can be avoided by pulse shaping the TX data to slow the change in the VCO load to a pace that the PLL can track with its given loop bandwidth. The loop bandwidth can also be increased to allow it to track faster changes due to load pulling.

For the ASK/OOK receiver demodulator, an external data slicer is required. The RSSI output is used to provide both the filtered data and a very low pass filtered (relative to the data rate) DC reference to a data slicer. Because the very low pass filter has a slow time constant, a longer preamble may be required to allow for the DC reference to get to a stable state. Here, as in the case of the FSK transmitter, the data pattern also affects the DC reference and the reliability of the received data. Again, a coding scheme such as Manchester such should be used to improve data integrity.

### APPLICATION AND LAYOUT CONSIDERATIONS

Both the RX IN and TX OUT have a DC bias on them. Therefore, DC blocking caps are required. If the RF filter has DC blocking characteristics like a ceramic dielectric filter, then only 1 DC blocking capacitor would

be needed to separate the DC of RX IN and TX OUT. These are RF signals and care should be taken to route these signals keeping them physically short. Because of the 50 $\Omega$ /high impedance nature of these two signals, they may be connected together into a signal 50 $\Omega$  device such as a filter. An external LNA or PA can be used, if desired, but an external RX/TX switch may be required.

The VCO is a very sensitive block in this system. RF signals feeding back into the VCO either radiated or coupled by traces may cause the PLL to become unlocked. The trace(s) for the anode of the tuning varactor should also be kept short. The layout of the resonators and varactor are very important. The capacitor and varactor should be closest to the RF2925 pins and the trace length should be as short as possible. The inductors can be placed further away and any trace inductance can be compensated by reducing the value of the inductors. Printed inductors may also be used with careful design. For best results, the physical layout should be as symmetrical as possible. Figure 1 is a recommended layout pattern for the VCO components. When using loop bandwidths lower than the 5kHz shown on the eval board, better filtering of the Vcc at the resonators (and lower Vcc noise as well) will help reduce phase noise of the VCO. A series resistor of 100 $\Omega$  to 200 $\Omega$  and a 1 $\mu$ F or larger capacitor can be used.

**Figure 1. Recommended VCO Layout**

For the interface between the LNA/mixer, the coupling capacitor should be as close to the RF2925 pins as possible with the bias inductor being further away. Once again, the value of the inductor can be changed to compensate to trace inductance. The output impedance of the LNA is in the order of several k $\Omega$  which makes matching to 50 $\Omega$  very hard. If image filtering is desired, a high impedance filter is recommended.

The quad tank of the discriminator can be implemented with ceramic discriminators available from a couple of sources. This design works well for wideband applications and where the temperature range is limited. The temperature coefficient of a ceramic discriminator can be in the order of +/- 50ppm per degree C. An automatic frequency control loop can be implemented using the DC level of the FM OUT for feedback to an external varactor on the reference crystal. An alternative to the ceramic discriminator is a LC tank. Figure 2 shows a schematic implementation of a LC tank.

Figure 2. LC Type Discriminator Circuit

The DEMOD IN pin has a DC bias on it and must be DC blocked. This can be done either at the pin or at the ground side of the LC tank (this must also be done if a parallel resistor is used with a ceramic discriminator). The decision whether to use a LC or a ceramic discriminator should be based upon the frequency deviation in the system, discriminator Q needed, and frequency and temperature tolerances. Tuning of the LC tank is required to overcome the component tolerances in the tank.

### Predicting and Minimizing PLL Lock Time

The RF2925 implements a conventional PLL on chip, with a VCO followed by a prescaler dividing the output frequency down to be compared with a signal from the reference oscillator. The output of the phase discriminator is a sequence of pulse width modulated current pulses in the required direction to steer the VCO's control voltage to maintain phase lock, with a loop filter integrating the current pulses. The lock time of this PLL is a combination of the loop transient response time and the slew rate set by the phase discriminator output current combined with the magnitude of the loop filter capacitance. A good approximation for total lock time of the RF2925 is:

$$\text{Lock time} = D/f_c + 35000 \cdot C \cdot dV$$

Where D is a factor to account for the loop damping. For loops with low phase margin (30° to 40°), use D=2 whereas for loops with better phase margin (50° to 60°), use D=1.  $f_c$  is the loop cut frequency. C is the sum of all shunt capacitors in the loop filter. dV is the required step voltage change to produce the desired frequency change during the transient.

To lock faster, we need to minimize C.

1. To this end, use the divide by 128 rather than the 64, and a correspondingly lower frequency reference crystal to achieve the desired output frequency.
2. Design the loop filter for the minimum phase margin possible without causing loop instability problems; this allows C to be kept at a minimum.
3. Design the loop filter for the highest loop cut frequency possible without distorting low frequency modulation components; this also allows C to be kept at a minimum.

## Evaluation Board Crystal Oscillator

### Which Topology?

The RF2925 on-board reference oscillator is configured as common collector, internally biased, with the Base and Emitter accessible. This can conveniently be used to implement a Colpitts oscillator with the addition of two external capacitors and a crystal. This allows the use of relatively cheap and readily available crystals, has a minimum parts count and doesn't require the use of inductors.

### Colpitts Topology

The basic topology of the Colpitts oscillator used is below:

The transmitter is acting as an emitter-follower. The voltage gain is set by capacitors C3 and C4 which are acting as a tapped capacitive impedance transformer.

The maximum loop gain is achieved when C4 has twice the capacitance of C3. C3 in series with C4 determines the load capacitance across the crystal. For a parallel

resonant, fundamental mode crystal, the crystal manufacturer will design the crystal for a specific load capacitance where the crystal will meet its specifications of frequency accuracy, temperature stability, ESR and so forth. Any deviation from the nominal capacitance will pull the oscillation frequency, allowing the frequency to be tuned by placing an adjustable reactance in series with the crystal.

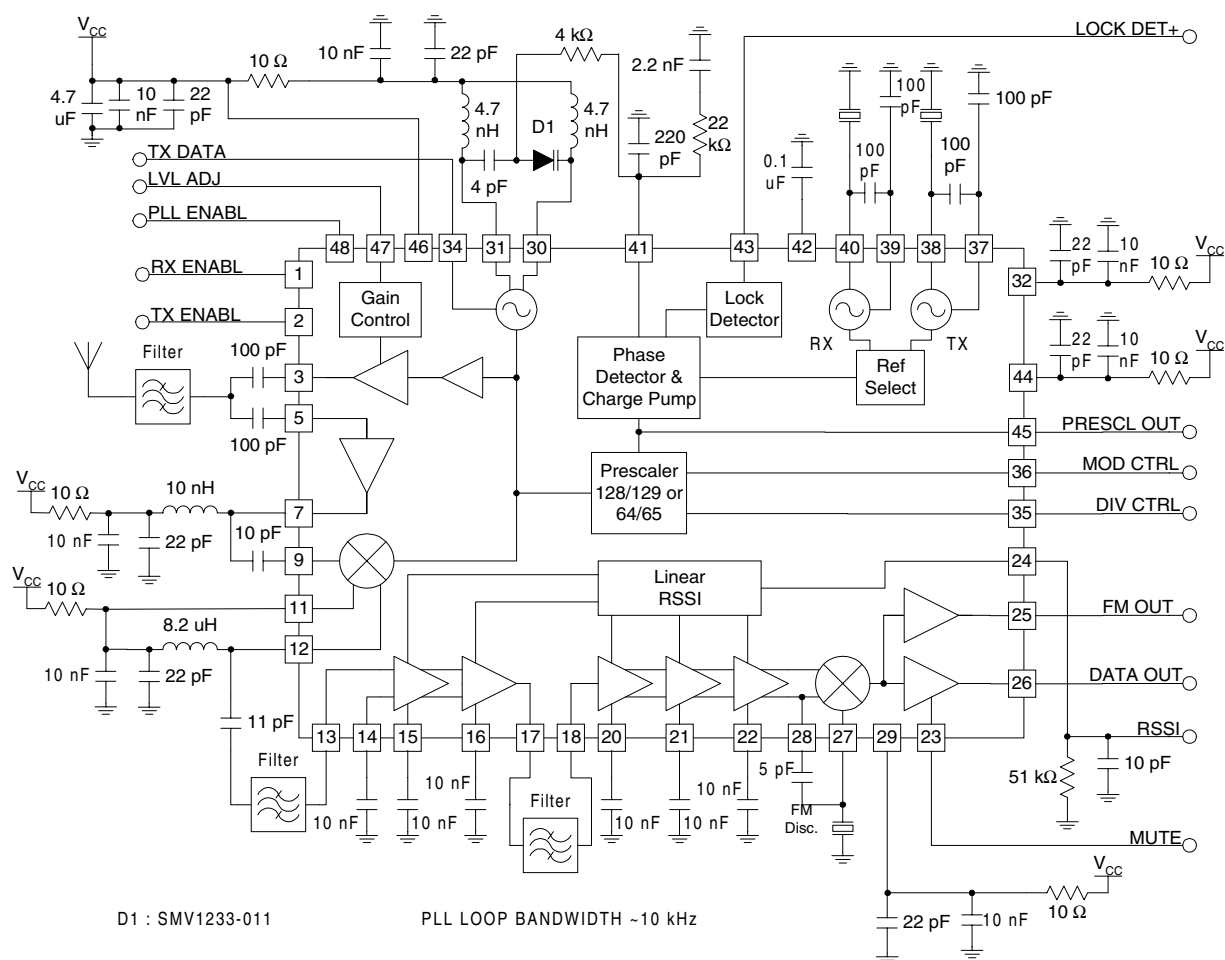

### Selection of a Crystal

The most obvious parameter to define is frequency, followed by frequency accuracy under nominal conditions and stability versus temperature. Another key parameter is the resonant mode of the crystal, either series or parallel. Series resonant mode is generally used when the crystal is being operated at an overtone of its resonant frequency, whereas parallel resonant mode is generally used with fundamental mode operation. Parallel resonant, fundamental mode is preferred as there is a multitude of this type of crystal available to cover the full range of operating frequencies of the RF2925, and it facilitates a simple oscillator topology. In this case "parallel resonant mode" needs to be specified along with nominal load capacitance and series resistance. An optional parameter to specify is pulling sensitivity, in PPM/pF, which defines how sensitive the crystal is to variation in load capacitance. Drive level should also be listed. When comparing crystals from different vendors, series resistance, frequency accuracy and temperature stability are all good indicators, but there are many other factors to trade off, including cost and packaging.

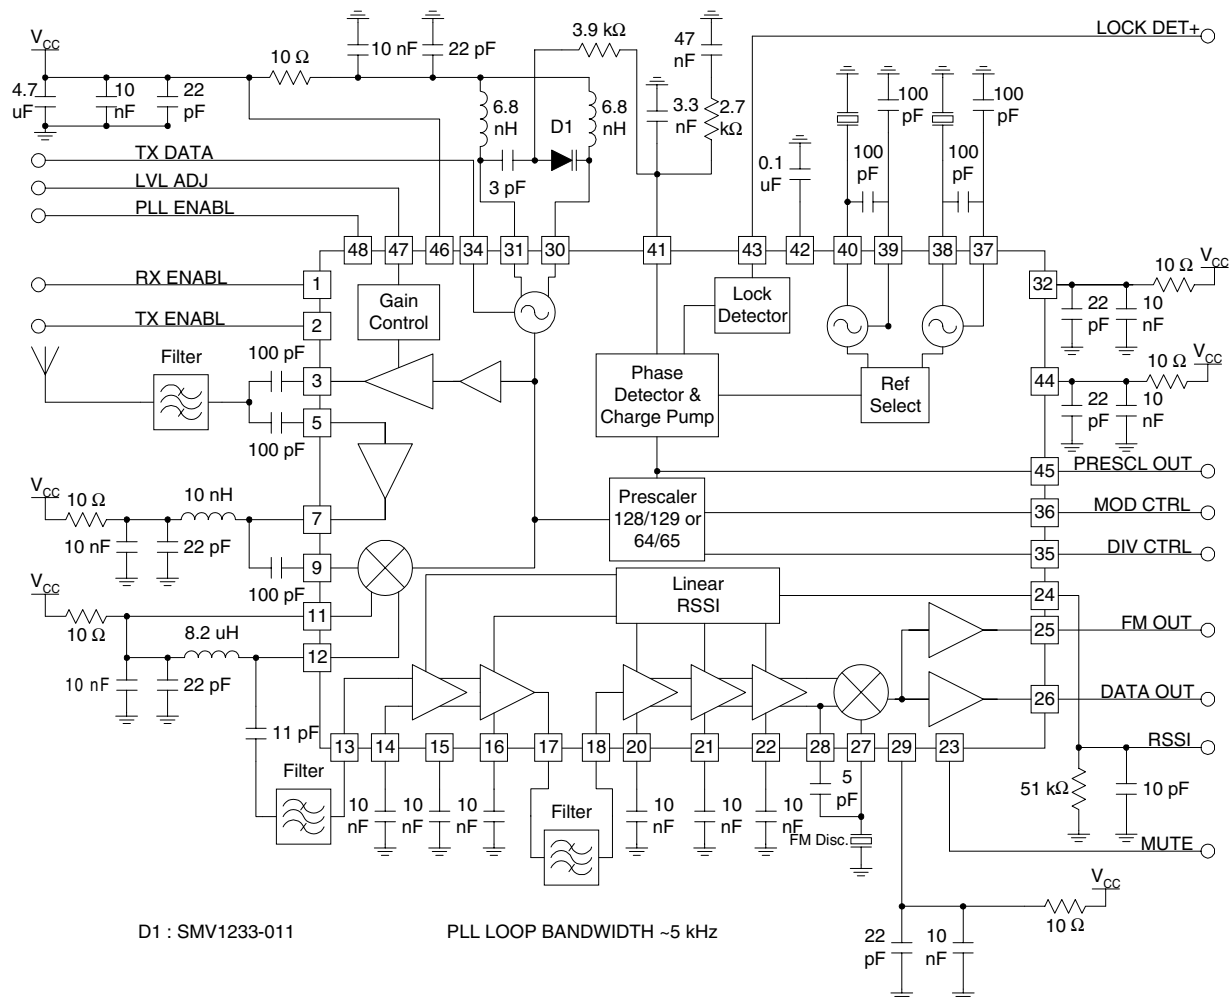

## Pin Out

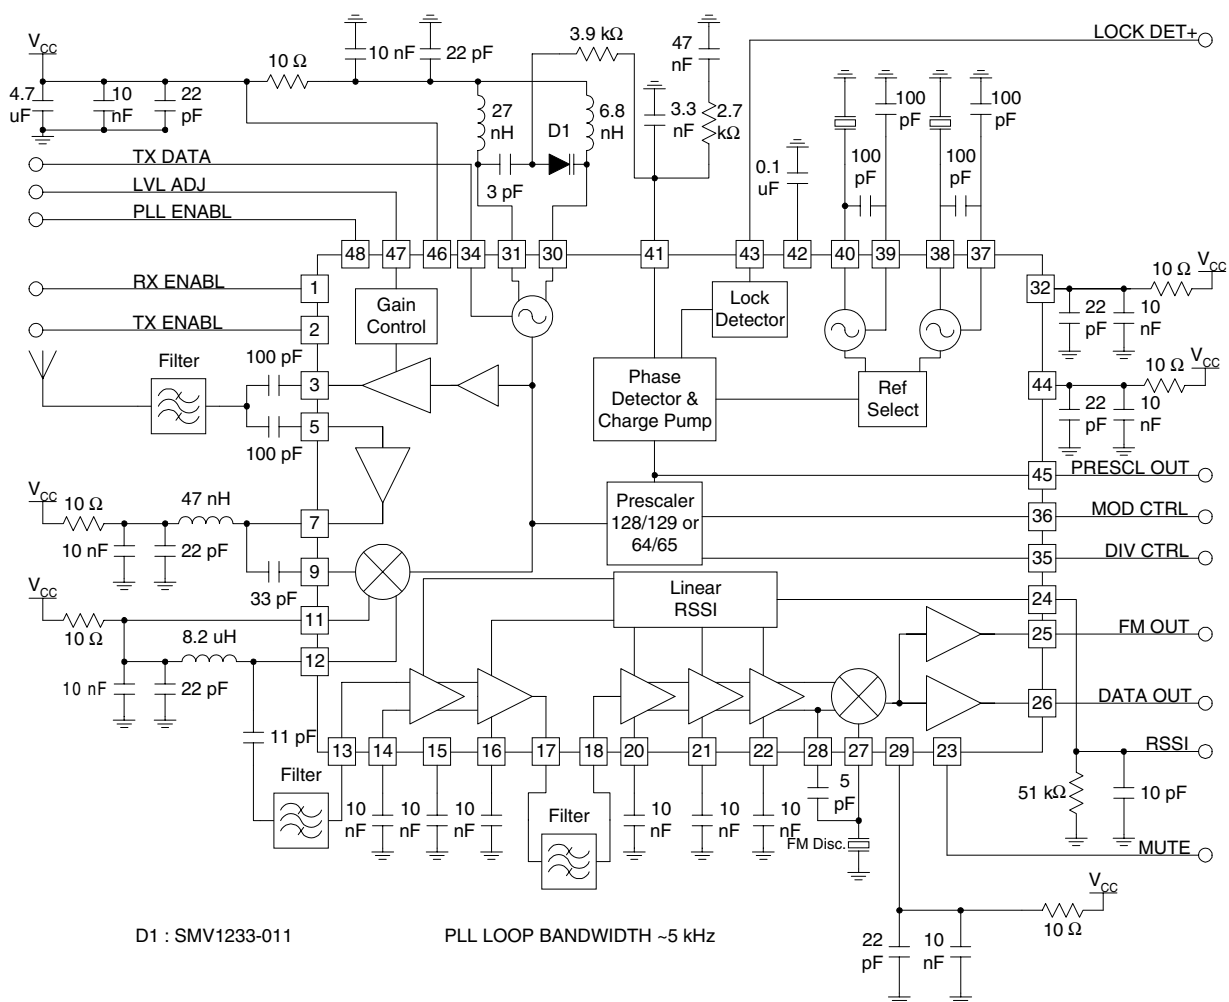

## 915 MHz Application Schematic

## 868 MHz Application Schematic

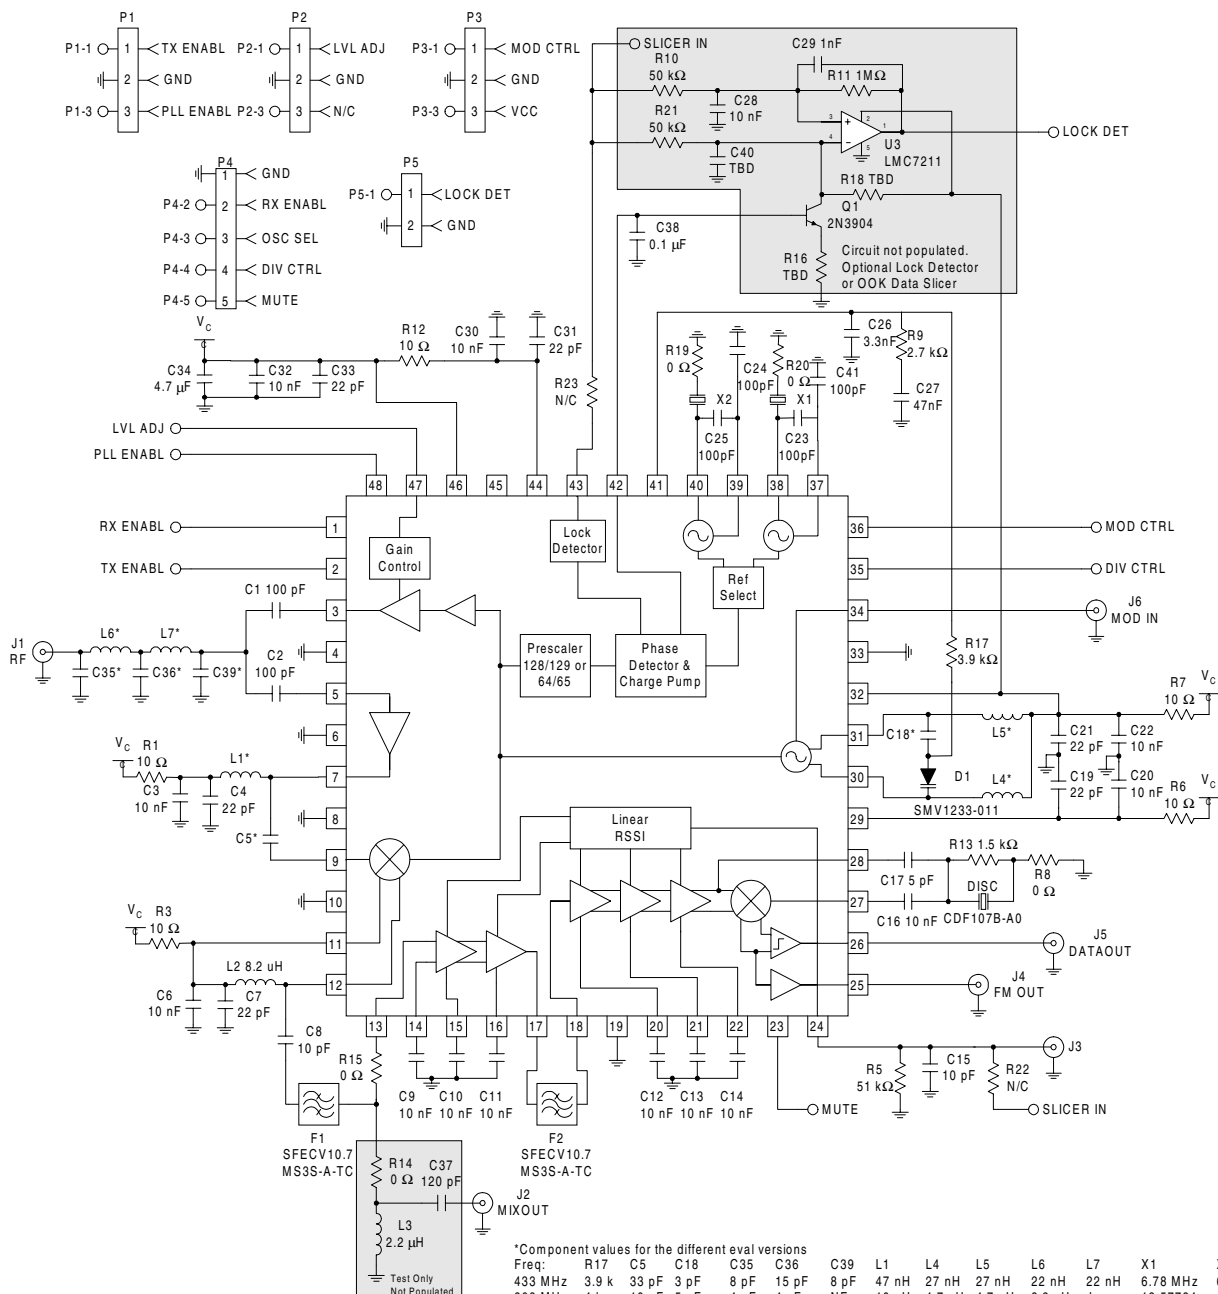

## 433 MHz Application Schematic

## Evaluation Board Schematic
