

TPA0242

STEREO 2-W AUDIO POWER AMPLIFIER WITH DC VOLUME CONTROL AND MUX CONTROL

SLOS287B – NOVEMBER 1999 – REVISED MAY 2001

- Compatible With PC 99 Desktop Line-Out Into 10-k Ω Load
- Compatible With PC 99 Portable Into 8- Ω Load
- Internal Gain Control, Which Eliminates External Gain-Setting Resistors
- DC Volume Control From 20 dB to –40 dB
- 2-W/Ch Output Power Into 3- Ω Load
- Input MUX Select Terminal
- PC-Beep Input
- Depop Circuitry
- Stereo Input MUX
- Fully Differential Input
- Low Supply Current and Shutdown Current
- Surface-Mount Power Packaging
24-Pin TSSOP PowerPAD™

description

The TPA0242 is a stereo audio power amplifier in a 24-pin TSSOP thermally enhanced package capable of delivering 2 W of continuous RMS power per channel into 3- Ω loads. This device minimizes the number of external components needed, which simplifies the design and frees up board space for other features. When driving 1 W into 8- Ω speakers, the TPA0242 has less than 0.22% THD+N across its specified frequency range.

Included within this device is integrated depop circuitry that virtually eliminates transients that cause noise in the speakers.

Amplifier gain is controlled by a dc voltage input on the VOLUME terminal. There are 31 discrete steps covering the range of 20 dB (maximum volume setting) to –40 dB (minimum volume setting) in 2 dB steps. When the VOLUME terminal exceeds 3.54 V, the device is muted. An internal input MUX allows two sets of stereo inputs to the amplifier. The HP/LINE terminal allows the user to select which MUX input is active regardless of whether the amplifier is in SE or BTL mode. In notebook applications, where internal speakers are driven as BTL and the line outputs (often headphone drive) are required to be SE, the TPA0242 automatically switches into SE mode when the SE/BTL input is activated, and this effectively reduces the gain by 6 dB.

The TPA0242 consumes only 20 mA of supply current during normal operation. A miserly shutdown mode reduces the supply current to less than 150 μ A.

The PowerPAD package (PWP) delivers a level of thermal performance that was previously achievable only in TO-220-type packages. Thermal impedances of approximately 35°C/W are truly realized in multilayer PCB applications. This allows the TPA0242 to operate at full power into 8- Ω loads at ambient temperatures of 85°C.

AVAILABLE OPTIONS

T _A	PACKAGED DEVICE
	TSSOP† (PWP)
–40°C to 85°C	TPA0242PWP

† The PWP package is available taped and reeled. To order a taped and reeled part, add the suffix R to the part number (e.g., TPA0242PWPR).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

functional block diagram

Terminal Functions

TERMINAL NAME	NO.	I/O	DESCRIPTION
BYPASS	11		Tap to voltage divider for internal mid-supply bias generator
CLK	17	I	If a 47-nF capacitor is attached, the TPA0242 generates an internal clock. An external clock can override the internal clock input to this terminal.
GND	1, 12 13, 24		Ground connection for circuitry. Connected to thermal pad
LHPIN	6	I	Left channel headphone input, selected when $\overline{\text{SE/BTL}}$ is held high
LIN	10	I	Common left input for fully differential input. AC ground for single-ended inputs
LLINEIN	5	I	Left channel line negative input, selected when $\overline{\text{SE/BTL}}$ is held low
LOUT+	4	O	Left channel positive output in $\overline{\text{BTL}}$ mode and positive output in SE mode
LOUT–	9	O	Left channel negative output in $\overline{\text{BTL}}$ mode and high-impedance in SE mode
HP/ $\overline{\text{LINE}}$	2	I	HP/ $\overline{\text{LINE}}$ is the input MUX control input. When the HP/ $\overline{\text{LINE}}$ terminal is held high, the headphone inputs (LHPIN or RHPIN [6, 20]) are active. When the HP/ $\overline{\text{LINE}}$ terminal is held low, the line BTL inputs (LLINEIN or RLINEIN [5, 23]) are active.
PC-BEEP	14	I	The input for PC-beep mode. PC-BEEP is enabled when a > 1-V (peak-to-peak) square wave is input to PC-BEEP.
PVDD	7, 18	I	Power supply for output stage
RHPIN	20	I	Right channel headphone input, selected when $\overline{\text{SE/BTL}}$ is held high
RIN	8	I	Common right input for fully differential input. AC ground for single-ended inputs
RLINEIN	23	I	Right channel line input, selected when $\overline{\text{SE/BTL}}$ is held low
ROUT+	21	O	Right channel positive output in $\overline{\text{BTL}}$ mode and positive output in SE mode
ROUT–	16	O	Right channel negative output in $\overline{\text{BTL}}$ mode and high-impedance in SE mode
$\overline{\text{SE/BTL}}$	15	I	Hold $\overline{\text{SE/BTL}}$ low for BTL mode and hold high for SE mode.
$\overline{\text{SHUTDOWN}}$	22	I	When held low, this terminal places the entire device, except PC-BEEP detect circuitry, in shutdown mode.
VDD	19	I	Analog VDD input supply. This terminal needs to be isolated from PVDD to achieve highest performance.
VOLUME	3	I	VOLUME detects the dc level at the terminal and sets the gain for 31 discrete steps covering a range of 20 dB to –40 dB for dc levels of 0.15 V to 3.54. When the dc level is over 3.54 V, the device is muted.

THERMAL INFORMATION

The thermally enhanced PWP package is based on the 24-pin TSSOP, but includes a thermal pad (see Figure 29) to provide an effective thermal contact between the IC and the PWB.

Traditionally, surface mount and power have been mutually exclusive terms. A variety of scaled-down TO-220-type packages have leads formed as gull wings to make them applicable for surface-mount applications. These packages, however, have only two shortcomings: they do not address the very low profile requirements (<2 mm) of many of today's advanced systems, and they do not offer a terminal-count high enough to accommodate increasing integration. On the other hand, traditional low-power surface-mount packages require power-dissipation derating that severely limits the usable range of many high-performance analog circuits.

The PowerPAD package (thermally enhanced TSSOP) combines fine-pitch surface-mount technology with thermal performance comparable to much larger power packages.

The PowerPAD package is designed to optimize the heat transfer to the PWB. Because of the very small size and limited mass of a TSSOP package, thermal enhancement is achieved by improving the thermal conduction paths that remove heat from the component. The thermal pad is formed using a patented lead-frame design and manufacturing technique to provide a direct connection to the heat-generating IC. When this pad is soldered or otherwise thermally coupled to an external heat dissipator, high power dissipation in the ultrathin, fine-pitch, surface-mount package can be reliably achieved.

SLOS287B – NOVEMBER 1999 – REVISED MAY 2001

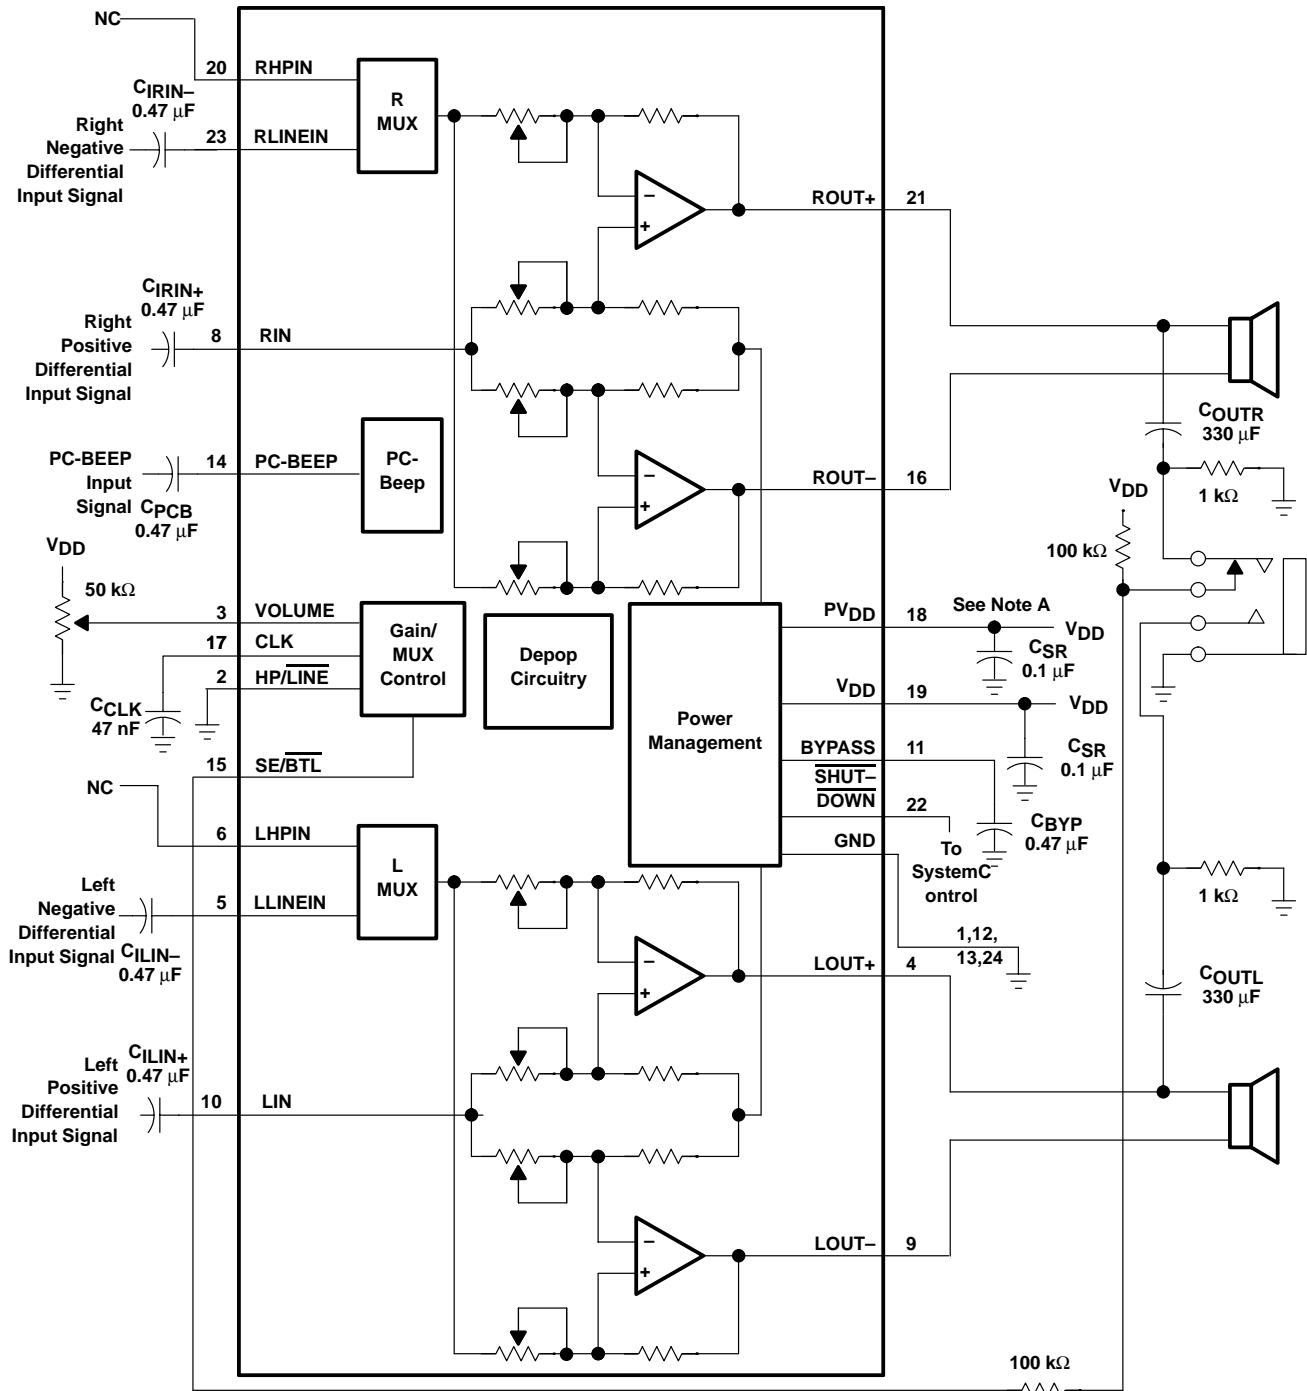

Figure 30. Typical TPA0242 Application Circuit Using Single-Ended Inputs and Input MUX

APPLICATION INFORMATION

NOTE A: A 0.1- μ F ceramic capacitor should be placed as close as possible to the IC. For filtering lower-frequency noise signals, a larger electrolytic capacitor of 10 μ F or greater should be placed near the audio power amplifier.

Figure 31. Typical TPA0242 Application Circuit Using Differential Inputs

APPLICATION INFORMATION

input resistance

Each gain setting is achieved by varying the input resistance of the amplifier, which can range from its smallest value to over six times that value. As a result, if a single capacitor is used in the input high pass filter, the –3 dB or cut-off frequency will also change by over six times. If an additional resistor is connected from the input pin of the amplifier to ground, as shown in Figure 32, the variation of the cutoff frequency will be reduced.

Figure 32. Resistor on Input for Cut-Off Frequency

The input resistance at each gain setting is given in Figure 28.

The –3-dB frequency can be calculated using equation 1.

$$f_{-3\text{ dB}} = \frac{1}{2\pi C(R \parallel R_i)} \quad (1)$$

If the filter must be more accurate, the value of the capacitor should be increased while the value of the resistor to ground should be decreased. In addition, the order of the filter could be increased.

input capacitor, C_i

In the typical application an input capacitor (C_i) is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation. In this case, C_i and the input impedance of the amplifier (Z_i) form a high-pass filter with the corner frequency determined in equation 2.

$$f_{c(\text{highpass})} = \frac{1}{2\pi Z_i C_i} \quad (2)$$

The value of C_i is important to consider as it directly affects the bass (low frequency) performance of the circuit. Consider the example where Z_i is 710 kΩ and the specification calls for a flat bass response down to 40 Hz. Equation 2 is reconfigured as equation 3.

$$C_i = \frac{1}{2\pi Z_i f_c} \quad (3)$$

APPLICATION INFORMATION

input capacitor, C_i (continued)

In this example, C_i is 5.6 nF so one would likely choose a value in the range of 5.6 nF to 1 μ F. A further consideration for this capacitor is the leakage path from the input source through the input network (C_i) and the feedback network to the load. This leakage current creates a dc offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications as the dc level there is held at $V_{DD}/2$, which is likely higher than the source dc level. Note that it is important to confirm the capacitor polarity in the application.

power supply decoupling, C_S

The TPA0242 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible. Power supply decoupling also prevents oscillations for long lead lengths between the amplifier and the speaker. The optimum decoupling is achieved by using two capacitors of different types that target different types of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance (ESR) ceramic capacitor, typically 0.1 μ F placed as close as possible to the device V_{DD} lead, works best. For filtering lower-frequency noise signals, a larger aluminum electrolytic capacitor of 10 μ F or greater placed near the audio power amplifier is recommended.

midrail bypass capacitor, C_{BYP}

The midrail bypass capacitor, C_{BYP} , is the most critical capacitor and serves several important functions. During startup or recovery from shutdown mode, C_{BYP} determines the rate at which the amplifier starts up. The second function is to reduce noise produced by the power supply caused by coupling into the output drive signal. This noise is from the midrail generation circuit internal to the amplifier, which appears as degraded PSRR and THD+N.

Bypass capacitor (C_{BYP}) values of 0.47- μ F to 1- μ F ceramic or tantalum low-ESR capacitors are recommended for the best THD and noise performance.

TPA0242

STEREO 2-W AUDIO POWER AMPLIFIER

WITH DC VOLUME CONTROL AND MUX CONTROL

SLOS287B – NOVEMBER 1999 – REVISED MAY 2001

APPLICATION INFORMATION

output coupling capacitor, $C_{(C)}$

In the typical single-supply SE configuration, an output coupling capacitor ($C_{(C)}$) is required to block the dc bias at the output of the amplifier thus preventing dc currents in the load. As with the input coupling capacitor, the output coupling capacitor and impedance of the load form a high-pass filter governed by equation 4.

$$f_{c(\text{high})} = \frac{1}{2\pi R_L C_{(C)}} \quad (4)$$

The main disadvantage, from a performance standpoint, is the load impedances are typically small, which drives the low-frequency corner higher, degrading the bass response. Large values of $C_{(C)}$ are required to pass low frequencies into the load. Consider the example where a $C_{(C)}$ of 330 μF is chosen and loads vary from 3 Ω , 4 Ω , 8 Ω , 32 Ω , 10 k Ω , and 47 k Ω . Table 2 summarizes the frequency response characteristics of each configuration.

Table 2. Common Load Impedances Vs Low Frequency Output Characteristics in SE Mode

R_L	$C_{(C)}$	Lowest Frequency
3 Ω	330 μF	161 Hz
4 Ω	330 μF	120 Hz
8 Ω	330 μF	60 Hz
32 Ω	330 μF	15 Hz
10,000 Ω	330 μF	0.05 Hz
47,000 Ω	330 μF	0.01 Hz

As Table 2 indicates, most of the bass response is attenuated into a 4- Ω load, an 8- Ω load is adequate, headphone response is good, and drive into line level inputs (a home stereo for example) is exceptional.

using low-ESR capacitors

Low-ESR capacitors are recommended throughout this applications section. A real (as opposed to ideal) capacitor can be modeled simply as a resistor in series with an ideal capacitor. The voltage drop across this resistor minimizes the beneficial effects of the capacitor in the circuit. The lower the equivalent value of this resistance the more the real capacitor behaves like an ideal capacitor.

APPLICATION INFORMATION

bridged-tied load versus single-ended mode

Figure 33 shows a Class-AB audio power amplifier (APA) in a BTL configuration. The TPA0242 BTL amplifier consists of two Class-AB amplifiers driving both ends of the load. There are several potential benefits to this differential drive configuration, but, initially consider power to the load. The differential drive to the speaker means that as one side is slewing up, the other side is slewing down, and vice versa. This in effect doubles the voltage swing on the load as compared to a ground referenced load. Plugging $2 \times V_{O(PP)}$ into the power equation, where voltage is squared, yields $4\times$ the output power from the same supply rail and load impedance (see equation 5).

$$V_{(rms)} = \frac{V_{O(PP)}}{2\sqrt{2}} \quad (5)$$

$$\text{Power} = \frac{V_{(rms)}^2}{R_L}$$

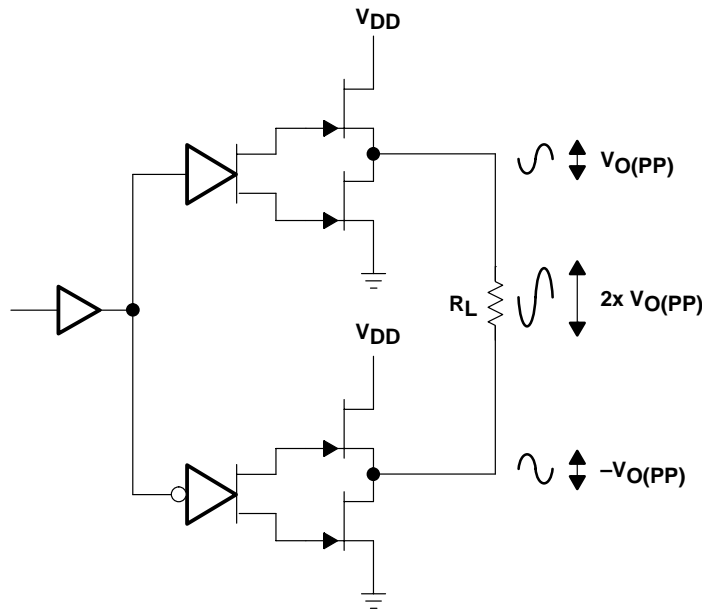

Figure 33. Bridge-Tied Load Configuration

In a typical computer sound channel operating at 5 V, bridging raises the power into an 8-Ω speaker from a singled-ended (SE, ground reference) limit of 250 mW to 1 W. In sound power that is a 6-dB improvement — which is loudness that can be heard. In addition to increased power there are frequency response concerns. Consider the single-supply SE configuration shown in Figure 34. A coupling capacitor is required to block the dc offset voltage from reaching the load. These capacitors can be quite large (approximately 33 μF to 1000 μF) so they tend to be expensive, heavy, occupy valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system. This frequency limiting effect is due to the high pass filter network created with the speaker impedance and the coupling capacitance and is calculated with equation 6.

$$f_{(c)} = \frac{1}{2\pi R_L C_{(C)}} \quad (6)$$

APPLICATION INFORMATION

bridged-tied load versus single-ended mode (continued)

For example, a 68- μF capacitor with an 8- Ω speaker would attenuate low frequencies below 293 Hz. The BTL configuration cancels the dc offsets, which eliminates the need for the blocking capacitors. Low-frequency performance is then limited only by the input network and speaker response. Cost and PCB space are also minimized by eliminating the bulky coupling capacitor.

Figure 34. Single-Ended Configuration and Frequency Response

Increasing power to the load does carry a penalty of increased internal power dissipation. The increased dissipation is understandable considering that the BTL configuration produces 4 \times the output power of the SE configuration. Internal dissipation versus output power is discussed further in the *crest factor and thermal considerations* section.

single-ended operation

In SE mode (see Figure 33 and Figure 34), the load is driven from the primary amplifier output for each channel (LOUT+ and ROUT+).

The amplifier switches single-ended operation when the SE/BTL terminal is held high. This puts the negative outputs in a high-impedance state, and reduces the amplifier's gain by 6 dB.

input MUX operation

The input MUX allows two separate inputs to be applied to the amplifier. This allows the designer to choose which input is active independent of the state of the SE/BTL terminal. When the HP/LINE terminal is held high, the headphone inputs are active. When the HP/LINE terminal is held low, the line BTL inputs are active.

BTL amplifier efficiency

Class-AB amplifiers are notoriously inefficient. The primary cause of these inefficiencies is voltage drop across the output stage transistors. There are two components of the internal voltage drop. One is the headroom or dc voltage drop that varies inversely to output power. The second component is due to the sinewave nature of the output. The total voltage drop can be calculated by subtracting the RMS value of the output voltage from V_{DD} . The internal voltage drop multiplied by the RMS value of the supply current (I_{DDrms}) determines the internal power dissipation of the amplifier.

An easy-to-use equation to calculate efficiency starts out as being equal to the ratio of power from the power supply to the power delivered to the load. To accurately calculate the RMS and average values of power in the load and in the amplifier, the current and voltage waveform shapes must first be understood (see Figure 35).

APPLICATION INFORMATION

BTL amplifier efficiency (continued)

Figure 35. Voltage and Current Waveforms for BTL Amplifiers

Although the voltages and currents for SE and BTL are sinusoidal in the load, currents from the supply are very different between SE and BTL configurations. In an SE application the current waveform is a half-wave rectified shape, whereas in BTL it is a full-wave rectified waveform. This means RMS conversion factors are different. Keep in mind that for most of the waveform both the push and pull transistors are not on at the same time, which supports the fact that each amplifier in the BTL device only draws current from the supply for half the waveform. The following equations are the basis for calculating amplifier efficiency.

$$\text{Efficiency of a BTL amplifier} = \frac{P_L}{P_{SUP}} \quad (7)$$

Where:

$$P_L = \frac{V_{Lrms}^2}{R_L}, \text{ and } V_{LRMS} = \frac{V_P}{\sqrt{2}}, \text{ therefore, } P_L = \frac{V_P^2}{2R_L}$$

$$\text{and } P_{SUP} = V_{DD} I_{DDavg} \quad \text{and} \quad I_{DDavg} = \frac{1}{\pi} \int_0^\pi \frac{V_P}{R_L} \sin(t) dt = \frac{1}{\pi} \times \frac{V_P}{R_L} [\cos(t)]_0^\pi = \frac{2V_P}{\pi R_L}$$

Therefore,

$$P_{SUP} = \frac{2 V_{DD} V_P}{\pi R_L}$$

substituting P_L and P_{SUP} into equation 7,

$$\text{Efficiency of a BTL amplifier} = \frac{\frac{V_P^2}{2R_L}}{\frac{2 V_{DD} V_P}{\pi R_L}} = \frac{\pi V_P}{4 V_{DD}}$$

Where:

$$V_P = \sqrt{2 P_L R_L}$$

Therefore,

$$\eta_{BTL} = \frac{\pi \sqrt{2 P_L R_L}}{4 V_{DD}} \quad (8)$$

P_L = Power delivered to load

P_{SUP} = Power drawn from power supply

V_{LRMS} = RMS voltage on BTL load

R_L = Load resistance

V_P = Peak voltage on BTL load

I_{DDavg} = Average current drawn from the power supply

V_{DD} = Power supply voltage

η_{BTL} = Efficiency of a BTL amplifier

TPA0242

STEREO 2-W AUDIO POWER AMPLIFIER

WITH DC VOLUME CONTROL AND MUX CONTROL

SLOS287B – NOVEMBER 1999 – REVISED MAY 2001

APPLICATION INFORMATION

BTL amplifier efficiency (continued)

Table 3 employs equation 8 to calculate efficiencies for four different output power levels. Note that the efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased resulting in a nearly flat internal power dissipation over the normal operating range. Note that the internal dissipation at full output power is less than in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design. For a stereo 1-W audio system with 8-Ω loads and a 5-V supply, the maximum draw on the power supply is almost 3.25 W.

Table 3. Efficiency vs Output Power in 5-V, 8-Ω BTL Systems

Output Power (W)	Efficiency (%)	Peak Voltage (V)	Internal Dissipation (W)
0.25	31.4	2.00	0.55
0.50	44.4	2.83	0.62
1.00	62.8	4.00	0.59
1.25	70.2	4.47†	0.53

† High peak voltages cause the THD to increase.

A final point to remember about Class-AB amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to utmost advantage when possible. Note that in equation 8, V_{DD} is in the denominator. This indicates that as V_{DD} goes down, efficiency goes up.

crest factor and thermal considerations

Class-AB power amplifiers dissipate a significant amount of heat in the package under normal operating conditions. A typical music CD requires 12 dB to 15 dB of dynamic range, or headroom above the average power output, to pass the loudest portions of the signal without distortion. In other words, music typically has a crest factor between 12 dB and 15 dB. When determining the optimal ambient operating temperature, the internal dissipated power at the average output power level must be used. From the TPA0242 data sheet, one can see that when the TPA0242 is operating from a 5-V supply into a 3-Ω speaker that 4-W peaks are available. Use equation 9 to convert watts to dB.

$$P_{dB} = 10 \log \frac{P_W}{P_{ref}} = 10 \log \frac{4 \text{ W}}{1 \text{ W}} = 6 \text{ dB} \quad (9)$$

Subtracting the headroom restriction to obtain the average listening level without distortion yields:

- 6 dB – 15 dB = –9 dB (15-dB crest factor)
- 6 dB – 12 dB = –6 dB (12-dB crest factor)
- 6 dB – 9 dB = –3 dB (9-dB crest factor)
- 6 dB – 6 dB = 0 dB (6-dB crest factor)
- 6 dB – 3 dB = 3 dB (3-dB crest factor)

Converting dB back into watts:

$$\begin{aligned}
 P_W &= 10^{P_{dB}/10} \times P_{ref} \\
 &= 63 \text{ mW (18-dB crest factor)} \\
 &= 125 \text{ mW (15-dB crest factor)} \\
 &= 250 \text{ mW (9-dB crest factor)} \\
 &= 500 \text{ mW (6-dB crest factor)} \\
 &= 1000 \text{ mW (3-dB crest factor)} \\
 &= 2000 \text{ mW (15-dB crest factor)}
 \end{aligned} \quad (10)$$

APPLICATION INFORMATION

crest factor and thermal considerations (continued)

This is valuable information to consider when attempting to estimate the heat dissipation requirements for the amplifier system. Comparing the absolute worst case, which is 2 W of continuous power output with a 3-dB crest factor, against 12-dB and 15-dB applications drastically affects maximum ambient temperature ratings for the system. Using the power dissipation curves for a 5-V, 3-Ω system, the internal dissipation in the TPA0242 and maximum ambient temperatures is shown in Table 4.

Table 4. TPA0242 Power Rating, 5-V, 3-Ω Stereo

PEAK OUTPUT POWER (W)	AVERAGE OUTPUT POWER	POWER DISSIPATION (W/Channel)	MAXIMUM AMBIENT TEMPERATURE
4	2 W (3 dB)	1.7	–3°C
4	1000 mW (6 dB)	1.6	6°C
4	500 mW (9 dB)	1.4	24°C
4	250 mW (12 dB)	1.1	51°C
4	125 mW (15 dB)	0.8	78°C
4	63 mW (18 dB)	0.6	96°C

Table 5. TPA0242 Power Rating, 5-V, 8-Ω Stereo

PEAK OUTPUT POWER (W)	AVERAGE OUTPUT POWER	POWER DISSIPATION (W/Channel)	MAXIMUM AMBIENT TEMPERATURE
2.5	1250 mW (3 dB crest factor)	0.55	100°C
2.5	1000 mW (4 dB crest factor)	0.62	94°C
2.5	500 mW (7 dB crest factor)	0.59	97°C
2.5	250 mW (10 dB crest factor)	0.53	102°C

The maximum dissipated power (P_{Dmax}) is reached at a much lower output power level for an 8-Ω load than for a 3-Ω load. As a result, this simple formula for calculating P_{Dmax} may be used for an 8-Ω application:

$$P_{Dmax} = \frac{2V_{DD}^2}{\pi^2 R_L} \quad (11)$$

However, in the case of a 3-Ω load, the P_{Dmax} occurs at a point well above the normal operating power level. The amplifier may therefore be operated at a higher ambient temperature than required by the P_{Dmax} formula for a 3-Ω load.

The maximum ambient temperature depends on the heat sinking ability of the PCB system. The derating factor for the PWP package is shown in the dissipation rating table. Converting this to Θ_{JA} :

$$\Theta_{JA} = \frac{1}{\text{Derating Factor}} = \frac{1}{0.022} = 45^\circ\text{C/W} \quad (12)$$

To calculate maximum ambient temperatures, first consider that the numbers from the dissipation graphs are per channel so the dissipated heat needs to be doubled for two channel operation. Given Θ_{JA} , the maximum allowable junction temperature, and the total internal dissipation, the maximum ambient temperature can be calculated using equation 13. The maximum recommended junction temperature for the TPA0242 is 150°C. The internal dissipation figures are taken from the Power Dissipation vs Output Power graphs.

$$\begin{aligned} T_{A \text{ Max}} &= T_{J \text{ Max}} - \Theta_{JA} P_D \\ &= 150 - 45(0.6 \times 2) = 96^\circ\text{C} \text{ (15-dB crest factor)} \end{aligned} \quad (13)$$

NOTE:

Internal dissipation of 0.6 W is estimated for a 2-W system with 15-dB crest factor per channel.

APPLICATION INFORMATION

crest factor and thermal considerations (continued)

Tables 4 and 5 show that for some applications no airflow is required to keep junction temperatures in the specified range. The TPA0242 is designed with thermal protection that turns the device off when the junction temperature surpasses 150°C to prevent damage to the IC. Tables 4 and 5 were calculated for maximum listening volume without distortion. When the output level is reduced the numbers in the table change significantly. Also, using 8-Ω speakers dramatically increases the thermal performance by increasing amplifier efficiency.

SE/BTL operation

The ability of the TPA0242 to easily switch between BTL and SE modes is one of its most important cost saving features. This feature eliminates the requirement for an additional headphone amplifier in applications where internal stereo speakers are driven in BTL mode but external headphone or speakers must be accommodated. Internal to the TPA0242, two separate amplifiers drive OUT+ and OUT–. The SE/BTL input (terminal 15) controls the operation of the follower amplifier that drives LOUT– and ROUT– (terminals 9 and 16). When SE/BTL is held low, the amplifier is on and the TPA0242 is in the BTL mode. When SE/BTL is held high, the OUT– amplifiers are in a high output impedance state, which configures the TPA0242 as an SE driver from LOUT+ and ROUT+ (terminals 4 and 21). I_{DD} is reduced by approximately one-half in SE mode. Control of the SE/BTL input can be from a logic-level CMOS source or, more typically, from a resistor divider network as shown in Figure 36.

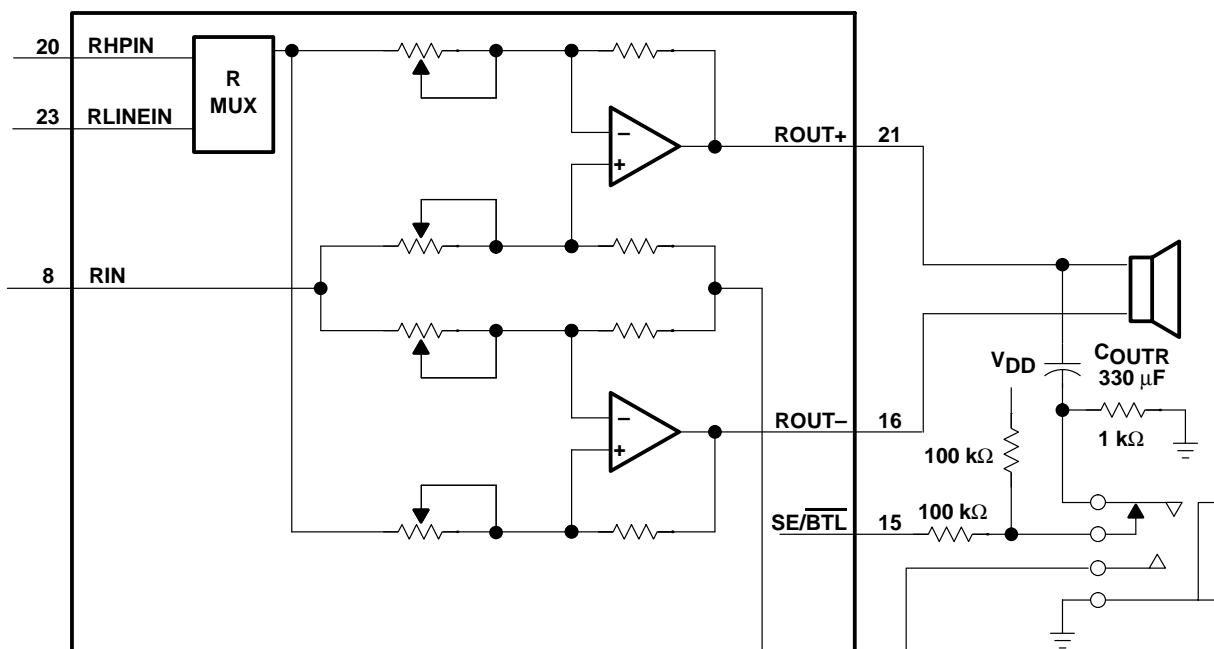

Figure 36. TPA0242 Resistor Divider Network Circuit

Using a readily available 1/8-in. (3,5 mm) stereo headphone jack, the control switch is closed when no plug is inserted. When closed the 100-kΩ/1-kΩ divider pulls the SE/BTL input low. When a plug is inserted, the 1-kΩ resistor is disconnected and the SE/BTL input is pulled high. When the input goes high, the OUT– amplifier is shut down causing the speaker to mute (virtually open-circuits the speaker). The OUT+ amplifier then drives through the output capacitor (C_O) into the headphone jack.

APPLICATION INFORMATION

PC-BEEP operation

The PC-BEEP input allows a system beep to be sent directly from a computer through the amplifier to the speakers with few external components. The input is activated automatically. When the PC-BEEP input is active, both of the LINEIN and HPIN inputs are deselected and both the left and right channels are driven in BTL mode with the signal from PC-BEEP. The gain from the PC-BEEP input to the speakers is fixed at 0.3 V/V and is independent of the volume setting. When the PC-BEEP input is deselected, the amplifier will return to the previous operating mode and volume setting. Furthermore, if the amplifier is in shutdown mode, activating PC-BEEP will take the device out of shutdown and output the PC-BEEP signal, then return the amplifier to shutdown mode.

When PCB ENABLE is held low, the amplifier will automatically switch to PC-BEEP mode after detecting a valid signal at the PC-BEEP input. The preferred input signal is a square wave or pulse train with an amplitude of 1 V_{pp} or greater. To be accurately detected, the signal must have a minimum of 1-V_{pp} amplitude, rise and fall times of less than 0.1 μs and a minimum of eight rising edges. When the signal is no longer detected, the amplifier will return to its previous operating mode and volume setting.

If it is desired to ac-couple the PC-BEEP input, the value of the coupling capacitor should be chosen to satisfy equation 14.

$$C_{PCB} \geq \frac{1}{2\pi f_{PCB} (100 \text{ k}\Omega)} \quad (14)$$

The PC-BEEP input can also be dc-coupled to avoid using this coupling capacitor. The pin normally sits at midrail when no signal is present.

shutdown modes

The TPA0242 employs a shutdown mode of operation designed to reduce supply current (I_{DD}) to the absolute minimum level during periods of nonuse for battery-power conservation. The SHUTDOWN input terminal should be held high during normal operation when the amplifier is in use. Pulling SHUTDOWN low causes the outputs to mute and the amplifier to enter a low-current state, I_{DD} = 150 μA. SHUTDOWN should never be left unconnected because amplifier operation would be unpredictable.

Table 6. HP/LINE, SE/BTL, and Shutdown Functions

INPUTS†			AMPLIFIER STATE	
HP/LINE	SE/BTL	SHUTDOWN	INPUT	OUTPUT
X	X	Low	X	Mute
Low	Low	High	Line	BTL
Low	High	High	Line	SE
High	Low	High	HP	BTL
High	High	High	HP	SE

† Inputs should never be left unconnected.
