## description/ordering information

The TL7702B, TL7705B, and TL7733B are integrated-circuit supply-voltage supervisors designed for use as reset controllers in microcomputer and microprocessor systems. The supply-voltage supervisor monitors the supply for undervoltage conditions at the SENSE input. During power up, the  $\overline{\text{RESET}}$  output becomes active (low) when  $V_{CC}$  attains a value approaching 1 V. As  $V_{CC}$  approaches 3 V (assuming that SENSE is above  $V_{T+}$ ), the delay-timer function activates a time delay, after which outputs  $\overline{\text{RESET}}$  and RESET go inactive (high and low, respectively). When an undervoltage condition occurs during normal operation, outputs  $\overline{\text{RESET}}$  and RESET go active. To ensure that a complete reset occurs, the reset outputs remain active for a time delay after the voltage at the SENSE input exceeds the positive-going threshold value. The time delay is determined by the value of the external capacitor  $C_T$ .  $t_d \approx 2.6 \times 10^4 \times C_T$ , where  $C_T$  is in farads (F) and  $t_d$  is in seconds (s).

An external capacitor (typically 0.1  $\mu\text{F}$ ) must be connected to REF to reduce the influence of fast transients in the supply voltage.

The TL7702BC, TL7705BC, and TL7733BC are characterized for operation from 0°C to 70°C. The TL7702BI, TL7705BI, and TL7733BI are characterized for operation from –40°C to 85°C. The TL7705BQ is characterized for operation from –40°C to 125°C. The TL7705BM is characterized for operation from –55°C to 125°C.

## absolute maximum ratings over operating free-air temperature range (unless otherwise noted)<sup>†</sup>

Supply voltage, $V_{CC}$ (see Note 1)	20 V
Input voltage range, $V_I$ : $\overline{\text{RESIN}}$	–0.3 V to 20 V
SENSE	–0.3 V to 20 V
High-level output current, $I_{OH}$ (RESET)	–30 mA
Low-level output current, $I_{OL}$ (RESET)	30 mA
Package thermal impedance, $\theta_{JA}$ (see Notes 2 and 3): D package	97°C/W
P package	85°C/W
Operating virtual junction temperature, $T_J$	150°C
Case temperature for 60 seconds, $T_C$ : FK package	260°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: JG or U packages	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: D or P packages	260°C
Storage temperature range, $T_{stg}$	–65°C to 150°C

<sup>†</sup> Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

- NOTES: 1. All voltage values are with respect to the network ground terminal.  
2. Maximum power dissipation is a function of  $T_J(\text{max})$ ,  $\theta_{JA}$ , and  $T_A$ . The maximum allowable power dissipation at any allowable ambient temperature is  $P_D = (T_J(\text{max}) - T_A)/\theta_{JA}$ . Operating at the absolute maximum  $T_J$  of 150°C can affect reliability.  
3. The package thermal impedance is calculated in accordance with JESD 51-7.

# TYPICAL CHARACTERISTICS†

Figure 4

Figure 5

Figure 6

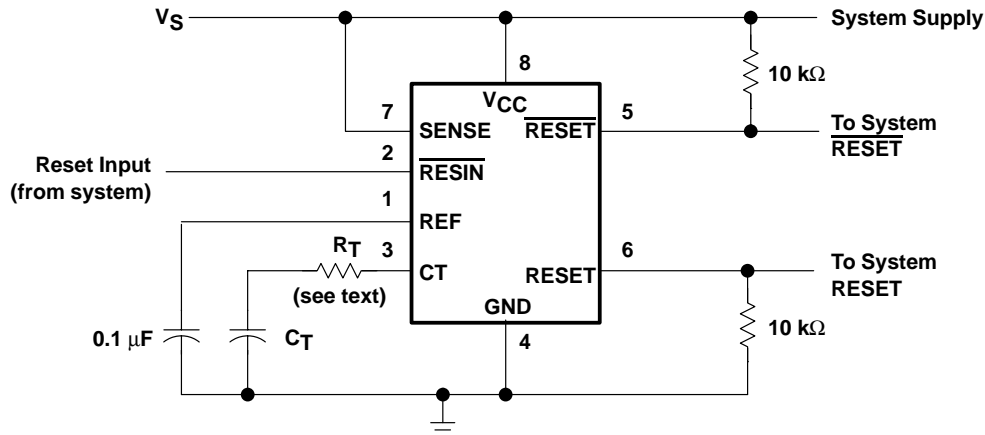

Figure 7

† For proper operation, both RESET and  $\overline{\text{RESET}}$  should be terminated with resistors of similar value. Failure to do so may cause unwanted plateauing in either output waveform during switching.

## APPLICATION INFORMATION

**Figure 8. System Reset Controller With Undervoltage Sensing**

When the TL770xB SENSE terminal is used to monitor  $V_{CC}$ , a current-limiting resistor in series with  $C_T$  is recommended. During normal operation, the timing capacitor is charged by the onboard current source to approximately  $V_{CC}$  or an internal voltage clamp ( $\approx 7.1$ -V Zener), whichever is less. When the circuit then is subjected to an undervoltage condition during which  $V_{CC}$  is rapidly slewed down, the voltage on CT exceeds that on  $V_{CC}$ . This forward biases a secondary path internally, which falsely activates the outputs. A fault is indicated when  $V_{CC}$  drops below  $V_{(CT)}$ , not when  $V_{SENSE}$  falls below  $V_{T-}$ .

Texas Instruments performs a 100% electrical screen to verify that the outputs do not switch with 1 mA forced into the CT terminal. Adding the external resistor,  $R_T$ , prevents false triggering. Its value is calculated as follows:

$$\frac{V_{(CT)} - V_{T-}}{R_T}$$

Where:

$$\begin{aligned} V_{(CT)} &= V_{CC} \text{ or } 7.1 \text{ V, whichever is less} \\ V_{T-} &= 4.55 \text{ V (nom)} \\ R_T &= \text{value of series resistor required} \end{aligned}$$

For  $V_{CC} = 5 \text{ V}$ :

$$\frac{5 - 4.55}{R_T} < 1 \text{ mA}$$

Therefore,

$$R_T > 450 \text{ } \Omega$$

Using a 20%-tolerance resistor,  $R_T$  should be greater than 560  $\Omega$ .

Adding this series resistor changes the duration of the reset pulse by no more than 10%.  $R_T$  extends the discharge of  $C_T$ , but also skews the  $V_{(CT)}$  threshold. These effects tend to cancel one another. The precise percentage change can be derived theoretically, but the equation is complicated by this interaction and is dependent upon the duration of the supply-voltage fault condition.

Both outputs of the TL770xB should be terminated with similar value resistors, even when only one is being used. This prevents unwanted plateauing in either output waveform during switching, which may be interpreted as an undefined state or delay system reset.
