

features

- 10-bit, 21 Mega-Samples Per Second (MSPS), A/D Converter
- Single Power Supply Operation, 2.7 V to 3.3 V
- Internally Programmable Correlated Double Sampler (CDS) Timing SR and ADCCLK
- Very Low Power: 109 mW Typical at 2.7-V, 1.5-mW Power-Down Mode
- Full Channel Differential Nonlinearity Error: $<\pm 0.5$ LSB Typical
- Full Channel Integral Nonlinearity Error: $<\pm 1.0$ LSB Typical
- Programmable Optical Black (OB) Level and Offset Calibration
- Programmable Gain Amplifier (PGA) With 0-dB to 36-dB Gain Range (0.047 dB/Step) for CCD Mode, 0-dB to 12-dB Gain Range (0.047 dB/Step) for Video Mode
- Additional Digital-to-Analog Converters (DACs) for External Analog Setting
- Serial Interface for Register Configuration
- Internal Reference Voltages
- 48-Terminal TQFP Package

applications

- Digital Still Camera
- Digital Camcorder
- Digital Video Camera

description

The VSP10T21 device is a complete charge-coupled device (CCD) and video signal processor/digitizer designed for digital camera and camcorder applications. The VSP10T21 device performs all the analog processing functions necessary to maximize the dynamic range, corrects various errors associated with the CCD sensor, and then digitizes the results with an on-chip high-speed analog-to-digital converter (ADC). One of the key features of this device is an integrated programmable delay generated for the CDS timing control, which eases the AFE timing adjustments for optimum image quality. Other key components of the VSP10T21 device include:

- Input clamp circuitry and a CDS
- Programmable gain amplifier (PGA) with 0-dB to 36-dB gain range (0.047 dB/step) for CCD mode, 0-dB to 12-dB gain range (0.047 dB/step) for video mode
- Internal programmable optical black level and offset calibration
- 10-bit, 21 MSPS pipeline ADC for CCD mode and 28 MSPS ADC for video mode
- Parallel data port for easy microprocessor interface and a serial port for configuring internal control registers
- Two DACs for external system control
- Internal reference voltages

Designed in advanced CMOS process, the VSP10T21 device operates from a single power supply with a normal power consumption of 109 mW at 2.7 V and 21 MSPS and a 1.5-mW power-down mode.

High precision, single 3-V operation, very low power consumption, and fully integrated analog processing circuitry make the VSP10T21 device an ideal CCD signal processing solution for the electronic video camcorder and digital still camera applications.

The part is available in a 48-terminal TQFP package and is specified over an operating temperature range of -20°C to 75°C .

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Terminal Functions

TERMINAL NAME NO.		I/O	DESCRIPTION
ADCCLK	22	O	ADCCLK clock output, for probe only
AVDD	24, 27, 33, 40		Analog supply voltage, +3 V
AVSS	25, 26, 35, 41		Analog ground
BLKG	19	I	Control input. The CDS operation is disabled when $\overline{\text{BLKG}}$ is pulled low.
CLAMP	23	I	CCD signal clamp control input
CLREF	28	O	Clamp reference voltage output
$\overline{\text{CS}}$	46	I	Chip select. A logic low on this input enables the VSP10T21 device.
DACO1	34	O	Digital-to-analog converter output 1
DACO2	36	O	Digital-to-analog converter output 2
DIN–	29	I	Differential input signal from CCD
DIN+	30	I	Differential Input signal from CCD
DIVDD	13		Digital interface circuit supply voltage, 1.8 V to 3.6 V
DIVSS	14		Digital interface circuit ground
DVDD	17		Digital supply voltage, +3 V
DVSS	15		Digital ground
D0–D9	3–12	O	10-bit 3-state ADC output data or offset DACs test data
MCLK	16	I	System clock input
NC	1, 2, 18		Not connected
OBCLP	20	I	Optical black level and offset calibration control input, active low
$\overline{\text{OE}}$	42	I	Output data enable, active low
PIN	31	I	Video input signal
RBD	37	O	Internal bandgap reference for external decoupling
$\overline{\text{RESET}}$	43	I	Hardware reset input, active low. This signal forces a reset of all internal registers.
RMD	39	O	Ref– output for external decoupling
RPD	38	O	Ref+ output for external decoupling
SCKP	45	I	This terminal selects the polarity of SCLK. 0 = Active low (high when SCLK is not running) 1 = Active high (low when SCLK is not running)
SCLK	48	I	Serial clock input. This clock synchronizes the serial data transfer.
SDIN	47	I	Serial data input to configure the internal registers.
SR	21	O	CCD reference level sample clock output, for probe only
$\overline{\text{STBY}}$	44	I	Hardware power-down control input, active low
VSS	32		Analog ground

key timing requirement

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
Maximum programming range for SR and ADCCLK timing signals			T^\dagger		ns
SR and ADCCLK programming resolution			$T/30$		ns
t_{SRW} SR pulse width	Measured at 50% of pulse height, recommend to use $T/4$ of ADCCLK cycle	10			ns
t_{SRD} Delay between the rising edge of external SR test output and the actual sampling instant	Measured at 50% of pulse height			2.4^\ddagger	ns
t_{ADCKD} Delay between the falling edge of external ADCCLK test output and the actual instant of sampling the video signal				1.7^\S	ns
t_{OD} The rising edge of MCLK to output data delay			6		ns
t_{CSF} CS falling edge to SCLK rising edge		0			ns
t_{CSR} SCLK falling edge to CS rising edge		5			ns

$^\dagger T$ is the time period of MCLK.

‡ SR is the internally generated timing. Due to the pad delay on the output SR, the maximum of the SR delay is 2.4 ns. It must not be delayed further on the positive direction unless it crosses a full pixel period (refer to Figure 2). The target for the SR position is to make sure that the rising edge of SR sample the reference level of the CCD signal.

§ ADCCLK is the internally generated timing. Due to the pad delay on the output ADCCLK, the maximum of the ADCCLK delay is 1.7 ns. It must not be delayed further on the positive direction unless it crosses a full pixel period (refer to Figure 2). The target for the SR position is to make sure that the falling edge of ADCCLK sample the video level of the active instant of the CCD signal.

NOTE: The digital output is latched out by MCLK.

APPLICATION INFORMATION

† ADCCLK and SR are test outputs only.

‡ DIVDD is recommended to have a ferrite bead to filter the power transients.

NOTE: All analog outputs should be buffered if the load is resistive or if the load is capacitive with more than 2 pF loading.
The decoupling capacitors for the power supplies must be placed as close as possible to these terminals.

† Bit D5 is recommended to be set to 1.

‡ This bit controls the polarity of the MCLK inside the VSP10T21 device which latches the ADC data output. Corresponding with this change, the user needs to read the data with different edge of the MCLK. By switching this bit from 0 to 1 also introduces an additional half pixel clock cycle delay.

PRINCIPLES OF OPERATION

CDS/PGA signal processor

In a CCD imaging system, the output from the CCD sensor is first fed to the CDS of the VSP10T21 device. The CCD signal is sampled and held during the reset reference interval and the video signal interval. By subtracting two resulting voltage levels, the CDS removes low frequency noise from the output of the CCD sensor and obtains the voltage difference between the CCD reference level and the video level of each pixel. Only the MCLK is required to feed into the AFE. Two clocks are generated internally based on the MCLK to perform the CDS function. One is SR for sampling the reference level of the CCD signal. The other clock is ADCCLK which samples the video level of the CCD signal on the falling edge. The ADCCLK is also used for the A/D conversion. These two clocks are output on the pad for the verification purpose. The user must not use these two terminals to drive any circuits. The digital ADC outputs are internally latched out by MCLK.

The CCD output is capacitively coupled to the VSP10T21 input. The $\overline{\text{CLAMP}}$ input clamps the ac-coupling capacitor to establish proper dc bias during the dummy pixel interval. The bias at the input to the VSP10T21 device is set to 1.2 V. Normally, the $\overline{\text{CLAMP}}$ is applied at sensor's line rate. A capacitor, with a value 10 times larger than that of the input ac-coupling capacitor, must be connected between terminals 28 (CLREF) and 25 (AVSS).

The signal is sent to the PGA after the CDS function is complete. The PGA gain can be adjusted from 0 dB to 36 dB by programming the internal gain register via the serial port. The PGA is digitally controlled with 10-bit resolution on a linear dB scale, resulting a 0.047 dB gain step. The gain can be expressed by the following equation:

$$\text{Gain} = \text{PGA code} \times 0.047 \text{ dB}$$

where PGA code has a range of 0 to 767.

For example, if PGA code = 128, then the PGA Gain = 6 dB (or gain of 2).

In CCD mode, users must use the 0 to 767 range for PGA gain code. The gain stays at 36 dB when the code is from 768 to 1023.

video mode operation

The VSP10T21 device also provides an analog video-processing channel that consists of an input clamp, a PGA, and an ADC. Setting the MOD bit to 1 in video control register enables the video channel. The video signal must be connected to terminal 31 (PIN) via a 0.1- μF capacitor as shown in Figure 4.

The video clamp circuit automatically clamps the lowest level of the video input signal, which is usually the sync tip, to around 60 LSB.

The PGA gain in the video mode can be adjusted from 0 to 12 dB by programming the internal gain register via the serial port. The PGA is digitally controlled with 10-bit resolution on a linear dB scale, resulting a 0.047 dB gain step. The gain can be expressed by the following equation:

$$\text{Gain} = (\text{PGA code} - 256) \times 0.047 \text{ dB}$$

where PGA code has a range of 256 to 512.

For the video mode, users must use the 256 to 512 range for the PGA gain code. The gain code 0–255 must not be used, and the gain range is from 12 dB to 24 dB for the gain code range of 513 to 767; however, the offset might be too large for this gain range.

PRINCIPLES OF OPERATION

internal timing

As previously explained, the SR and ADCCLK clocks are required to operate the CDS. Users need to synchronize the SR and ADCCLK clocks with the CCD signal waveform. The output from the ADC is read out to external circuitry by the MCLK signal that is the external signal used to generate the SR and ADCCLK clocks internally. The user can use the SR and ADCCLK internal delay register to program the delay of these clocks based on Figure 2 in order to achieve the optimal performance. Terminals 21 (SR) and 22 (ADCCLK) are used to monitor these two internal signals. By changing bit D2 (CKIP) in the clock control register, the AFE digital output is latched at either the rising edge or the falling edge of the MCLK pulse.

The $\overline{\text{CLAMP}}$ signal activates the clamping circuit for the input signal. The $\overline{\text{OBCLP}}$ signal activates the optical black calibration and the active portion (the low pulse) of this signal must be within the optical black period of the CCD (see Figure 1).

ADC

The ADC employs a pipelined architecture to achieve high throughput and low power consumption. Fully differential implementation and digital error correction ensure 10-bit resolution.

The latency of the ADC data output is the default 5 MCLK cycles as shown in Figure 2. Pulling terminal 42 ($\overline{\text{OE}}$) high puts the ADC output in high impedance.

automatic optical black calibration

In the VSP10T21 device, the optical black and the system channel offset corrections are performed by an auto analog feedback loop. During the optical black calibration interval ($\overline{\text{OBCLP}}$ = low) of each line, the optical black pixels plus the channel offset are sampled and compared with the desired black level specified in the optical black Vb setup register. The difference is then integrated and added to incoming pixel data at PGA input. This analog feedback loop calibrates the PGA output to the desired black pixel level, which can be programmed either to 0 or from 20 LSB to 35 LSB at 1 LSB/step resolution typically via the serial port. The OB calibration settles within about 1000 OB pixels.

input blanking function

During blanking period of CCD operation, large input transients may occur at the VSP10T21 device's input, making the ADC output unpredictable. Activating $\overline{\text{BLKG}}$ pulse during this period ensures the digital code is zero at the ADC output.

user DACs

The VSP10T21 device includes two user DACs that can be used for external analog settings. These are resistor string DACs. They must be used only to drive capacitor or buffer loads, not resistor loads. The output voltage of each DAC can be independently set and has a range of 0 V to the supply voltage with 8-bit resolution. When the user DACs are not used in a camera system, they can be put in the standby mode by programming control bits in the control register 1. The status of the user DACs is defined in the following table.

PRINCIPLES OF OPERATION

SOFTWARE/HARDWARE GLOBAL STANDBY	PDD1/PDD2	DACD	STATUS OF DAC1/DAC2
Active	0	x	Active
Active	1	x	Standby
Standby	0	0	Standby
Standby	0	1	Active
Standby	1	x	Standby

NOTE: The hardware global standby is set by pulling down terminal 44 (STBY) of the VSP10T21 device. The software global standby is controlled by setting bit D9 (STBY) in the control register to 1.

3-wire serial interface

A simple 3-wire (terminals 48 (SCLK), 47 (SDIN), and 46 (\overline{CS})) serial interface is provided to allow writing to the internal registers of the VSP10T21 device. The serial clock SCLK can be run at a maximum speed of 40 MHz. The serial data SDIN is 16 bits long. After two leading null bits, there are four address bits for which internal register is to be updated, the following 10 bits are the data to be written to the register. To enable the serial port, \overline{CS} must be held low. The data transfer is initiated by the incoming SCLK after \overline{CS} falls. Figure 3 shows the detailed timing for the serial interface.

The SCLK polarity is selectable by pulling terminal 45 (SCKP) either high or low.

device reset

The device is not under the default configuration when powered on. The registers are set to the default value by a reset. When terminal 43 (\overline{RESET}) is pulled low, all internal registers are set to their default values. In addition, the VSP10T21 device has a software-reset function that resets the device when writing to a control bit in the control register.

See *REGISTER DEFINITION* for the register default values.

power-down mode (standby)

The VSP10T21 device implements both hardware and software power-down modes. Pulling terminal 44 (\overline{STBY}) low puts the device in the low-power standby mode. The total power drops to about 1.5 mW. Setting bit D9 (STBY) in the control register can also activate the power-down mode. Users can still program all internal registers during the power-down mode.

power supply

The VSP10T21 device has several power supply terminals. Each major internal analog block has a dedicated AV_{DD} supply terminal. All internal digital circuitry is powered by the DV_{DD} . Both AV_{DD} and DV_{DD} are 3 V nominal.

The DIV_{DD} and DIV_{SS} terminals supply power to the output digital driver (D9–D0). The DIV_{DD} is independent of the DV_{DD} and can be operated from 1.8 V to 3.6 V. This allows the outputs to interface with digital ASICs requiring different supply voltages.

PRINCIPLES OF OPERATION

grounding and decoupling

General practices must apply to the printed-circuit board (PCB) design to limit high frequency transients and noise that are fed back into the supply and reference lines. This requires that the supply and reference terminals be sufficiently bypassed. In the case of power supply decoupling, 0.1- μ F ceramic chip capacitors are adequate to keep the impedance low over a wide frequency range. Recommended external decoupling for the three voltage reference terminals is shown in Figure 4. Since the effectiveness of the decoupling capacitors depends largely on the proximity to the individual supply terminal, all decoupling capacitors must be placed as close as possible to the supply terminals. An inductor is recommended for the DIV_{DD} power supply (see Figure 4). Common ground is also recommended.

voltage references

An internal precision voltage reference of 1.5 V nominal is provided. This reference voltage generates the ADC Ref– voltage of 1 V and Ref+ of 2 V. It also sets the clamp voltage. All internally generated voltages are fixed values and cannot be adjusted. Terminals 37 (RBD), 38 (RPD), and 39 (RMD) must not be used to drive any loads.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
