

4-20mA CURRENT TRANSMITTER with Sensor Excitation and Linearization

FEATURES

- LOW UNADJUSTED ERROR
- TWO PRECISION CURRENT SOURCES: 800 μ A each
- LINEARIZATION
- 2- OR 3-WIRE RTD OPERATION
- LOW OFFSET DRIFT: 0.4 μ V/ $^{\circ}$ C
- LOW OUTPUT CURRENT NOISE: 30nA_{pp}
- HIGH PSR: 110dB minimum
- HIGH CMR: 86dB minimum
- WIDE SUPPLY RANGE: 7.5V to 36V
- DIP-14 AND SO-14 PACKAGES

DESCRIPTION

The XTR105 is a monolithic 4-20mA, 2-wire current transmitter with two precision current sources. It provides complete current excitation for platinum RTD temperature sensors and bridges, instrumentation amplifiers, and current output circuitry on a single integrated circuit.

Versatile linearization circuitry provides a 2nd-order correction to the RTD, typically achieving a 40:1 improvement in linearity.

Instrumentation amplifier gain can be configured for a wide range of temperature or pressure measurements. Total unadjusted error of the complete current transmitter is low enough to permit use without adjustment in many applications. This includes zero output current drift, span drift, and nonlinearity. The XTR105 operates on loop power-supply voltages down to 7.5V.

The XTR105 is available in DIP-14 and SO-14 surface-mount packages and is specified for the -40° C to $+85^{\circ}$ C industrial temperature range.

APPLICATIONS

- INDUSTRIAL PROCESS CONTROL
- FACTORY AUTOMATION
- SCADA REMOTE DATA ACQUISITION
- REMOTE TEMPERATURE AND PRESSURE TRANSDUCERS

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Power Supply, V+ (referenced to the I _O pin)	40V
Input Voltage, V _{IN+} , V _{IN-} (referenced to the I _O pin)	0V to V+
Storage Temperature Range	-55°C to +125°C
Lead Temperature (soldering, 10s)	+300°C
Output Current Limit	Continuous
Junction Temperature	+165°C

NOTE: (1) Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. Exposure to absolute maximum conditions for extended periods may affect device reliability.

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

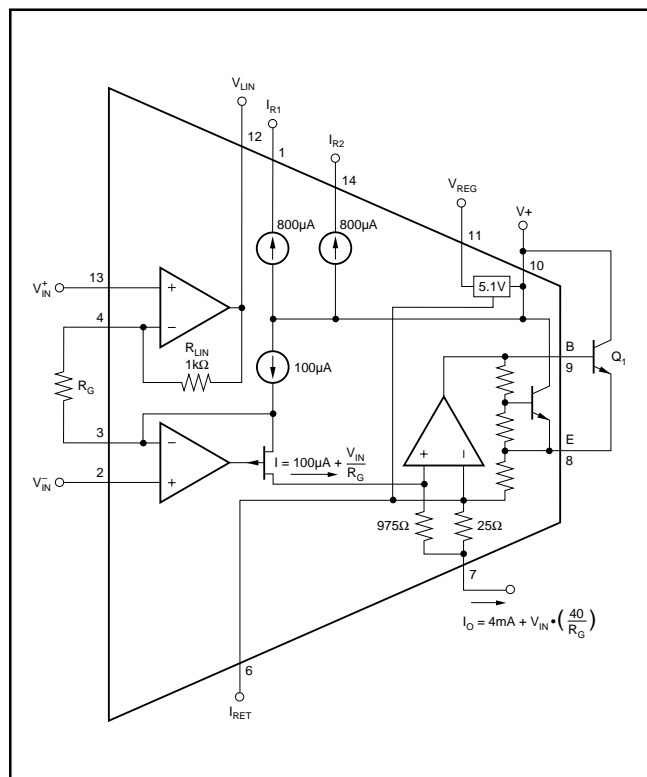

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

APPLICATION INFORMATION

Figure 1 shows the basic connection diagram for the XTR105. The loop power supply, V_{PS} , provides power for all circuitry. Output loop current is measured as a voltage across the series load resistor, R_L .

Two matched 0.8mA current sources drive the RTD and zero-setting resistor, R_Z . The instrumentation amplifier input of the XTR105 measures the voltage difference between the RTD and R_Z . The value of R_Z is chosen to be equal to the resistance of the RTD at the low-scale (minimum) measurement temperature. R_Z can be adjusted to achieve 4mA output at the minimum measurement temperature to correct for input offset voltage and reference current mismatch of the XTR105.

R_{CM} provides an additional voltage drop to bias the inputs of the XTR105 within their common-mode input range. R_{CM} should be bypassed with a 0.01μF capacitor to minimize common-mode noise. Resistor R_G sets the gain of the instrumentation amplifier according to the desired temperature range. R_{LIN1} provides 2nd-order linearization correction to the RTD, typically achieving a 40:1 improvement in linearity. An additional resistor is required for 3-wire RTD connections (see Figure 3).

The transfer function through the complete instrumentation amplifier and voltage-to-current converter is:

$$I_O = 4\text{mA} + V_{IN} \cdot (40/R_G)$$

(V_{IN} in volts, R_G in ohms)

where V_{IN} is the differential input voltage.

As evident from the transfer function, if no R_G is used the gain is zero and the output is simply the XTR105's zero current. The value of R_G varies slightly for 2-wire RTD and 3-wire RTD connections with linearization. R_G can be calculated from the equations given in Figure 1 (2-wire RTD connection) and Table I (3-wire RTD connection).

The I_{RET} pin is the return path for all current from the current sources and V_{REG} . The I_{RET} pin allows any current used in external circuitry to be sensed by the XTR105 and to be included in the output current without causing an error.

The V_{REG} pin provides an on-chip voltage source of approximately 5.1V and is suitable for powering external input circuitry (refer to Figure 6). It is a moderately accurate voltage reference—it is not the same reference used to set the 800μA current references. V_{REG} is capable of sourcing approximately 1mA of current. Exceeding 1mA may affect the 4mA zero output.

$$\begin{bmatrix} R_Z/R_G \\ R_{LIN1} \\ R_{LIN2} \end{bmatrix}$$

NOTE: The values listed in this table are 1% resistors (in Ω). Exact values may be calculated from the following equations:

R_Z = RTD resistance at minimum measured temperature.

$$R_G = \frac{2(R_Z - R_1)(R_1 - R_2)}{(R_2 - R_1)}$$

$$R_{LIN1} = \frac{R_{LIN}(R_2 - R_1)}{2(2R_1 - R_2 - R_Z)}$$

$$R_{LIN2} = \frac{(R_{LIN} + R_G)(R_2 - R_1)}{2(2R_1 - R_2 - R_Z)}$$

where: R_1 = RTD resistance at $(T_{MIN} + T_{MAX})/2$

R_2 = RTD resistance at T_{MAX}

R_{LIN} = 1k Ω (Internal)

EXAMPLE:

The measurement range is -100°C to +200°C for a 3-wire Pt100 RTD connection. Determine the values for R_Z , R_G , R_{LIN1} , and R_{LIN2} . Look up the values from the chart or calculate the values according to the equations provided.

METHOD 1: TABLE LOOK UP

For $T_{MIN} = -100^\circ\text{C}$ and $\Delta T = -300^\circ\text{C}$, the 1% values are:

$$R_Z = 60.4\Omega \quad R_{LIN1} = 10.5k\Omega$$

$$R_G = 243\Omega \quad R_{LIN2} = 13k\Omega$$

METHOD 2: CALCULATION

Step 1: Determine R_Z , R_1 , and R_2 .

R_Z is the RTD resistance at the minimum measured temperature, $T_{MIN} = -100^\circ\text{C}$. Using Equation 1 at right gives $R_Z = 60.25\Omega$ (1% value is 60.4 Ω).

R_2 is the RTD resistance at the maximum measured temperature, $T_{MAX} = 200^\circ\text{C}$. Using Equation 2 at right gives $R_2 = 175.84\Omega$.

R_1 is the RTD resistance at the midpoint measured temperature, $T_{MID} = (T_{MIN} + T_{MAX})/2 = 50^\circ\text{C}$. R_1 is NOT the average of R_Z and R_2 . Using Equation 2 at right gives $R_1 = 119.40\Omega$.

Step 2: Calculate R_G , R_{LIN1} , and R_{LIN2} using equations above.

$$R_G = 242.3\Omega \text{ (1% value is } 243\Omega\text{)}$$

$$R_{LIN1} = 10.413k\Omega \text{ (1% value is } 10.5k\Omega\text{)}$$

$$R_{LIN2} = 12.936k\Omega \text{ (1% value is } 13k\Omega\text{)}$$

Calculation of Pt100 Resistance Values

(according to DIN IEC 751)

(Equation 1) Temperature range from -200°C to 0°C:

$$R_{(T)} = 100 [1 + 3.90802 \cdot 10^{-3} \cdot T - 0.5802 \cdot 10^{-6} \cdot T^2 - 4.27350 \cdot 10^{-12} (T - 100)^3]$$

(Equation 2) Temperature range from 0°C to +850°C:

$$R_{(T)} = 100 (1 + 3.90802 \cdot 10^{-3} \cdot T - 0.5802 \cdot 10^{-6} \cdot T^2)$$

where: $R_{(T)}$ is the resistance in Ω at temperature T .
 T is the temperature in $^\circ\text{C}$.

NOTE: Most RTD manufacturers provide reference tables for resistance values at various temperatures.

TABLE I. R_Z , R_G , R_{LIN1} , and R_{LIN2} Standard 1% Resistor Values for 3-Wire Pt100 RTD Connection with Linearization.

A negative input voltage, V_{IN} , will cause the output current to be less than 4mA. Increasingly negative V_{IN} will cause the output current to limit at approximately 2.2mA. Refer to the typical characteristic Under-Scale Current vs Temperature.

Increasingly positive input voltage (greater than the full-scale input) will produce increasing output current according to the transfer function, up to the output current limit of approximately 27mA. Refer to the typical characteristic Over-Scale Current vs Temperature.

EXTERNAL TRANSISTOR

Transistor Q₁ conducts the majority of the signal-dependent 4-20mA loop current. Using an external transistor isolates the majority of the power dissipation from the precision input and reference circuitry of the XTR105, maintaining excellent accuracy.

Since the external transistor is inside a feedback loop, its characteristics are not critical. Requirements are: $V_{CEO} = 45V$ min, $\beta = 40$ min, and $P_D = 800mW$. Power dissipation requirements may be lower if the loop power-supply voltage is less than 36V. Some possible choices for Q₁ are listed in Figure 1.

The XTR105 can be operated without this external transistor, however, accuracy will be somewhat degraded due to the internal power dissipation. Operation without Q₁ is not recommended for extended temperature ranges. A resistor ($R = 3.3k\Omega$) connected between the I_{RET} pin and the E (emitter) pin may be needed for operation below 0°C without Q₁ to ensure the full 20mA full-scale output, especially with V+ near 7.5V.

FIGURE 2. Operation Without an External Transistor.

LOOP POWER SUPPLY

The voltage applied to the XTR105, V+, is measured with respect to the I_O connection, pin 7. V+ can range from 7.5V to 36V. The loop-supply voltage, V_{PS}, will differ from the voltage applied to the XTR105 according to the voltage drop on the current sensing resistor, R_L (plus any other voltage drop in the line).

If a low loop-supply voltage is used, R_L (including the loop wiring resistance) must be made a relatively low value to assure that V+ remains 7.5V or greater for the maximum loop current of 20mA:

$$R_L \max = \left(\frac{(V+) - 7.5V}{20mA} \right) - R_{WIRING}$$

It is recommended to design for V+ equal or greater than 7.5V with loop currents up to 30mA to allow for out-of-range input conditions.

The low operating voltage (7.5V) of the XTR105 allows operation directly from personal computer power supplies (12V ±5%). When used with the RCV420 current loop receiver (see Figure 7), the load resistor voltage drop is limited to 3V.

ADJUSTING INITIAL ERRORS

Many applications require adjustment of initial errors. Input offset and reference current mismatch errors can be corrected by adjustment of the zero resistor, R_Z. Adjusting the gain-setting resistor, R_G, corrects any errors associated with gain.

2- AND 3-WIRE RTD CONNECTIONS

In Figure 1, the RTD can be located remotely simply by extending the two connections to the RTD. With this remote 2-wire connection to the RTD, line resistance will introduce error. This error can be partially corrected by adjusting the values of R_Z, R_G, and R_{LIN1}.

A better method for remotely located RTDs is the 3-wire RTD connection (see Figure 3). This circuit offers improved accuracy. R_Z's current is routed through a third wire to the RTD. Assuming line resistance is equal in RTD lines 1 and 2, this produces a small common-mode voltage that is rejected by the XTR105. A second resistor, R_{LIN2}, is required for linearization.

Note that although the 2-wire and 3-wire RTD connection circuits are very similar, the gain-setting resistor, R_G, has slightly different equations:

$$\text{2-wire: } R_G = \frac{2R_1(R_2 + R_Z) - 4(R_2R_Z)}{R_2 - R_1}$$

$$\text{3-wire: } R_G = \frac{2(R_2 - R_Z)(R_1 - R_Z)}{R_2 - R_1}$$

where: R_Z = RTD resistance at T_{MIN}

R₁ = RTD resistance at (T_{MIN} + T_{MAX})/2

R₂ = RTD resistance at T_{MAX}

To maintain good accuracy, at least 1% (or better) resistors should be used for R_G. Table I provides standard 1% R_G resistor values for a 3-wire Pt100 RTD connection with linearization.

LINEARIZATION

RTD temperature sensors are inherently (but predictably) nonlinear. With the addition of one or two external resistors, R_{LIN1} and R_{LIN2}, it is possible to compensate for most of this nonlinearity resulting in 40:1 improvement in linearity over the uncompensated output.

See Figure 1 for a typical 2-wire RTD application with linearization. Resistor R_{LIN1} provides positive feedback and controls linearity correction. R_{LIN1} is chosen according to the desired temperature range. An equation is given in Figure 1.

In 3-wire RTD connections, an additional resistor, R_{LIN2} , is required. As with the 2-wire RTD application, R_{LIN1} provides positive feedback for linearization. R_{LIN2} provides an offset canceling current to compensate for wiring resistance encountered in remotely located RTDs. R_{LIN1} and R_{LIN2} are chosen such that their currents are equal. This makes the voltage drop in the wiring resistance to the RTD a common-mode signal that is rejected by the XTR105. The nearest standard 1% resistor values for R_{LIN1} and R_{LIN2} should be adequate for most applications. Table I provides the 1% resistor values for a 3-wire Pt100 RTD connection.

If no linearity correction is desired, the V_{LIN} pin should be left open. With no linearization, $R_G = 2500 \cdot V_{FS}$, where V_{FS} = full-scale input range.

RTDs

The text and figures thus far have assumed a Pt100 RTD. With higher resistance RTDs, the temperature range and input voltage variation should be evaluated to ensure proper common-mode biasing of the inputs. As mentioned earlier, R_{CM} can be adjusted to provide an additional voltage drop to bias the inputs of the XTR105 within their common-mode input range.

ERROR ANALYSIS

See Table II for how to calculate the effect various error sources have on circuit accuracy. A sample error calculation for a typical RTD measurement circuit (Pt100 RTD, 200°C measurement span) is provided. The results reveal the XTR105's excellent accuracy, in this case 1.1% unadjusted. Adjusting resistors R_G and R_Z for gain and offset errors improves circuit accuracy to 0.32%. Note that these are worst-case errors; ensured maximum values were used in the calculations and all errors were assumed to be positive (additive). The XTR105 achieves performance that is difficult to obtain with discrete circuitry and requires less space.

OPEN-CIRCUIT PROTECTION

The optional transistor Q_2 in Figure 3 provides predictable behavior with open-circuit RTD connections. It assures that if any one of the three RTD connections is broken, the XTR105's output current will go to either its high current limit ($\approx 27\text{mA}$) or low current limit ($\approx 2.2\text{mA}$). This is easily detected as an out-of-range condition.

FIGURE 3. Remotely Located RTDs with 3-Wire Connection.

TABLE II. Error Calculation.

REVERSE-VOLTAGE PROTECTION

The XTR105's low compliance rating (7.5V) permits the use of various voltage protection methods without compromising operating range. Figure 4 shows a diode bridge circuit that allows normal operation even when the voltage connection lines are reversed. The bridge causes a two diode drop (approximately 1.4V) loss in loop-supply voltage. This results in a compliance voltage of approximately 9V—satisfactory for most applications. If a 1.4V drop in loop supply is too much, a diode can be inserted in series with the loop-supply voltage and the V+ pin. This protects against reverse output connection lines with only a 0.7V loss in loop-supply voltage.

SURGE PROTECTION

Remote connections to current transmitters can sometimes be subjected to voltage surges. It is prudent to limit the maximum surge voltage applied to the XTR105 to as low as practical. Various zener diodes and surge clamping diodes are specially designed for this purpose. Select a clamp diode with as low a voltage rating as possible for best protection. For example, a 36V protection diode will assure proper transmitter operation at normal loop voltages, yet will provide an appropriate level of protection against voltage surges. Characterization tests on three production lots showed no damage to the XTR105 within loop-supply voltages up to 65V.

Most surge protection zener diodes have a diode characteristic in the forward direction that will conduct excessive current, possibly damaging receiving-side circuitry if the loop connections are reversed. If a surge protection diode is used, a series diode or diode bridge should be used for protection against reversed connections.

RADIO FREQUENCY INTERFERENCE

The long wire lengths of current loops invite radio frequency (RF) interference. RF can be rectified by the sensitive input circuitry of the XTR105 causing errors. This generally appears as an unstable output current that varies with the position of loop supply or input wiring.

If the RTD sensor is remotely located, the interference may enter at the input terminals. For integrated transmitter assemblies with short connections to the sensor, the interference more likely comes from the current loop connections.

Bypass capacitors on the input reduce or eliminate this input interference. Connect these bypass capacitors to the I_{RET} terminal (see Figure 5). Although the dc voltage at the I_{RET} terminal is not equal to 0V (at the loop supply, V_{PS}), this circuit point can be considered the transmitter's "ground." The $0.01\mu\text{F}$ capacitor connected between V+ and I_O may help minimize output interference.

 D. Falls within JEDEC MS-012

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
