DSP56311

Advance Information

24-BIT DIGITAL SIGNAL PROCESSOR

The Motorola DSP56311, a member of the DSP56300 family of programmable digital signal processors (DSPs), supports wireless infrastructure applications with general filtering operations. The on-chip enhanced filter coprocessor (EFCOP) processes filter algorithms in parallel with core operation, thus increasing overall DSP performance and efficiency. Like the other family members, the DSP56311 uses a high-performance, single-clock-cycle-per-instruction engine (code-compatible with Motorola's popular DSP56000 core family), a barrel shifter, 24-bit addressing, an instruction cache, and a direct memory access (DMA) controller, as shown in **Figure 1**. The DSP56311 performs at 150 million instructions per second (MIPS), attaining 255 MIPS when the EFCOP is used in filtering applications. It has an internal 150 MHz clock with a 1.8 volt core and independent 3.3 volt input/output (I/O) power.

Data Sheet Conventions

$\overline{\text{OVERBAR}}$	Indicates a signal that is active when pulled low (For example, the $\overline{\text{RESET}}$ pin is active when low.)
“asserted”	A high true (active high) signal is high or a low true (active low) signal is low
“deasserted”	A high true (active high) signal is low or a low true (active low) signal is high

Examples:

Signal/Symbol	Logic State	Signal State	Voltage*
$\overline{\text{PIN}}$	True	Asserted	V_{IL}/V_{OL}
$\overline{\text{PIN}}$	False	Deasserted	V_{IH}/V_{OH}
PIN	True	Asserted	V_{IH}/V_{OH}
PIN	False	Deasserted	V_{IL}/V_{OL}

Note: *Values for V_{IL}, V_{OL}, V_{IH}, and V_{OH} are defined by individual product specifications.

FEATURES

High-Performance DSP56300 Core

- 150 million instructions per second (MIPS) (255 MIPS using the EFCOP in filtering applications) with a 150 MHz clock at 1.8 V core and 3.3 V I/O
- Object code compatible with the DSP56000 core
- Highly parallel instruction set
- Data arithmetic logic unit (ALU)
  - Fully pipelined 24 x 24-bit parallel multiplier-accumulator
  - 56-bit parallel barrel shifter (fast shift and normalization; bit stream generation and parsing)
  - Conditional ALU instructions
  - 24-bit or 16-bit arithmetic support under software control
- Program control unit (PCU)
  - Position independent code (PIC) support
  - Addressing modes optimized for DSP applications (including immediate offsets)
  - On-chip instruction cache controller
  - On-chip memory-expandable hardware stack
  - Nested hardware DO loops
  - Fast auto-return interrupts
- Direct memory access (DMA)
  - Six DMA channels supporting internal and external accesses
  - One-, two-, and three- dimensional transfers (including circular buffering)
  - End-of-block-transfer interrupts
  - Triggering from interrupt lines and all peripherals
- Phase-locked loop (PLL)
  - Allows change of low-power divide factor (DF) without loss of lock
  - ~~Output clock with skew elimination~~
- Hardware debugging support
  - On-Chip Emulation (OnCE™) module
  - Joint test action group (JTAG) test access port (TAP)
  - ~~Address trace mode reflects internal Program RAM accesses at the external port~~

Enhanced Filtering Coprocessor (EFCOP)

The on-chip filtering and echo-cancellation coprocessor (EFCOP) runs in parallel to the DSP core.

On-Chip Memories

- 128 K on-chip RAM total
- Program RAM, Instruction Cache, X data RAM, and Y data RAM sizes are programmable:

Program RAM Size	Instruction Cache Size	X Data RAM Size*	Y Data RAM Size*	Instruction Cache	Switch Mode	MSW1	MSW0
32K × 24-bit	0	48K × 24-bit	48K × 24-bit	disabled	disabled	0/1	0/1
31K × 24-bit	1024 × 24-bit	48K × 24-bit	48K × 24-bit	enabled	disabled	0/1	0/1
96K × 24-bit	0	16K × 24-bit	16K × 24-bit	disabled	enabled	0	0
95K × 24-bit	1024 × 24-bit	16K × 24-bit	16K × 24-bit	enabled	enabled	0	0
80K × 24-bit	0	24K × 24-bit	24K × 24-bit	disabled	enabled	0	1
79K × 24-bit	1024 × 24-bit	24K × 24-bit	24K × 24-bit	enabled	enabled	0	1
64K × 24-bit	0	32K × 24-bit	32K × 24-bit	disabled	enabled	1	0
63K × 24-bit	1024 × 24-bit	32K × 24-bit	32K × 24-bit	enabled	enabled	1	0
48K × 24-bit	0	40K × 24-bit	40K × 24-bit	disabled	enabled	1	1
47K × 24-bit	1024 × 24-bit	40K × 24-bit	40K × 24-bit	enabled	enabled	1	1

*Includes 10K × 24-bit shared memory (that is, memory shared by the core and the EFCOP)

- 192 x 24-bit bootstrap ROM

Off-Chip Memory Expansion

- Data memory expansion to two 256K × 24-bit word memory spaces (or up to two 4 M × 24-bit word memory spaces by using the address attribute AA0–AA3 signals)
- Program memory expansion to one 256K × 24-bit words memory space (or up to one 4 M × 24-bit word memory space by using the address attribute AA0–AA3 signals)
- External memory expansion port
- Chip Select Logic for glueless interface to static random access memory (SRAMs)
- ~~On-chip DRAM Controller for glueless interface to dynamic random access memory (DRAMs)~~

DRAM Access Support

DRAM accesses are not supported in the DSP56311 at 150 MHz.

On-Chip Peripherals

- Enhanced DSP56000-like 8-bit parallel host interface (HI08) supports a variety of buses (for example, ISA) and provides glueless connection to a number of industry-standard microcomputers, microprocessors, and DSPs
- Two enhanced synchronous serial interfaces (ESSI), each with one receiver and three transmitters (allows six-channel home theater)
- Serial communications interface (SCI) with baud rate generator
- Triple timer module
- Up to 34 programmable general-purpose input/output (GPIO) pins, depending on which peripherals are enabled

Reduced Power Dissipation

- Very low-power CMOS design
- Wait and Stop low-power standby modes
- Fully static design specified to operate at 0 Hz (dc)
- Optimized power management circuitry (instruction-dependent, peripheral-dependent, and mode-dependent)

Packaging

The DSP56311 is available in a 196-pin PBGA package.

TARGET APPLICATIONS

The DSP56311 is intended for applications requiring a large amount of on-chip memory, such as wireless infrastructure applications. The EFCOP can accelerate general filtering applications, such as echo-cancellation applications, correlation, and general-purpose convolution-based algorithms.

PRODUCT DOCUMENTATION

The three documents listed in the following table are required for a complete description of the DSP56311 and are necessary to design properly with the part. Documentation is available from the following sources. (See the back cover for detailed information.)

- A local Motorola distributor
- A Motorola semiconductor sales office
- A Motorola Literature Distribution Center
- The World Wide Web (WWW)

DSP56311 Documentation

Name	Description	Order Number
DSP56300 Family Manual	Detailed description of the DSP56300 family processor core and instruction set	DSP56300FM/AD
DSP56311 User's Manual	Detailed functional description of the DSP56311 memory configuration, operation, and register programming	DSP56311UM/D
DSP56311 Technical Data	DSP56311 features list and physical, electrical, timing, and package specifications	DSP56311DS/D

SECTION 1

SIGNALS/CONNECTIONS

SIGNAL GROUPINGS

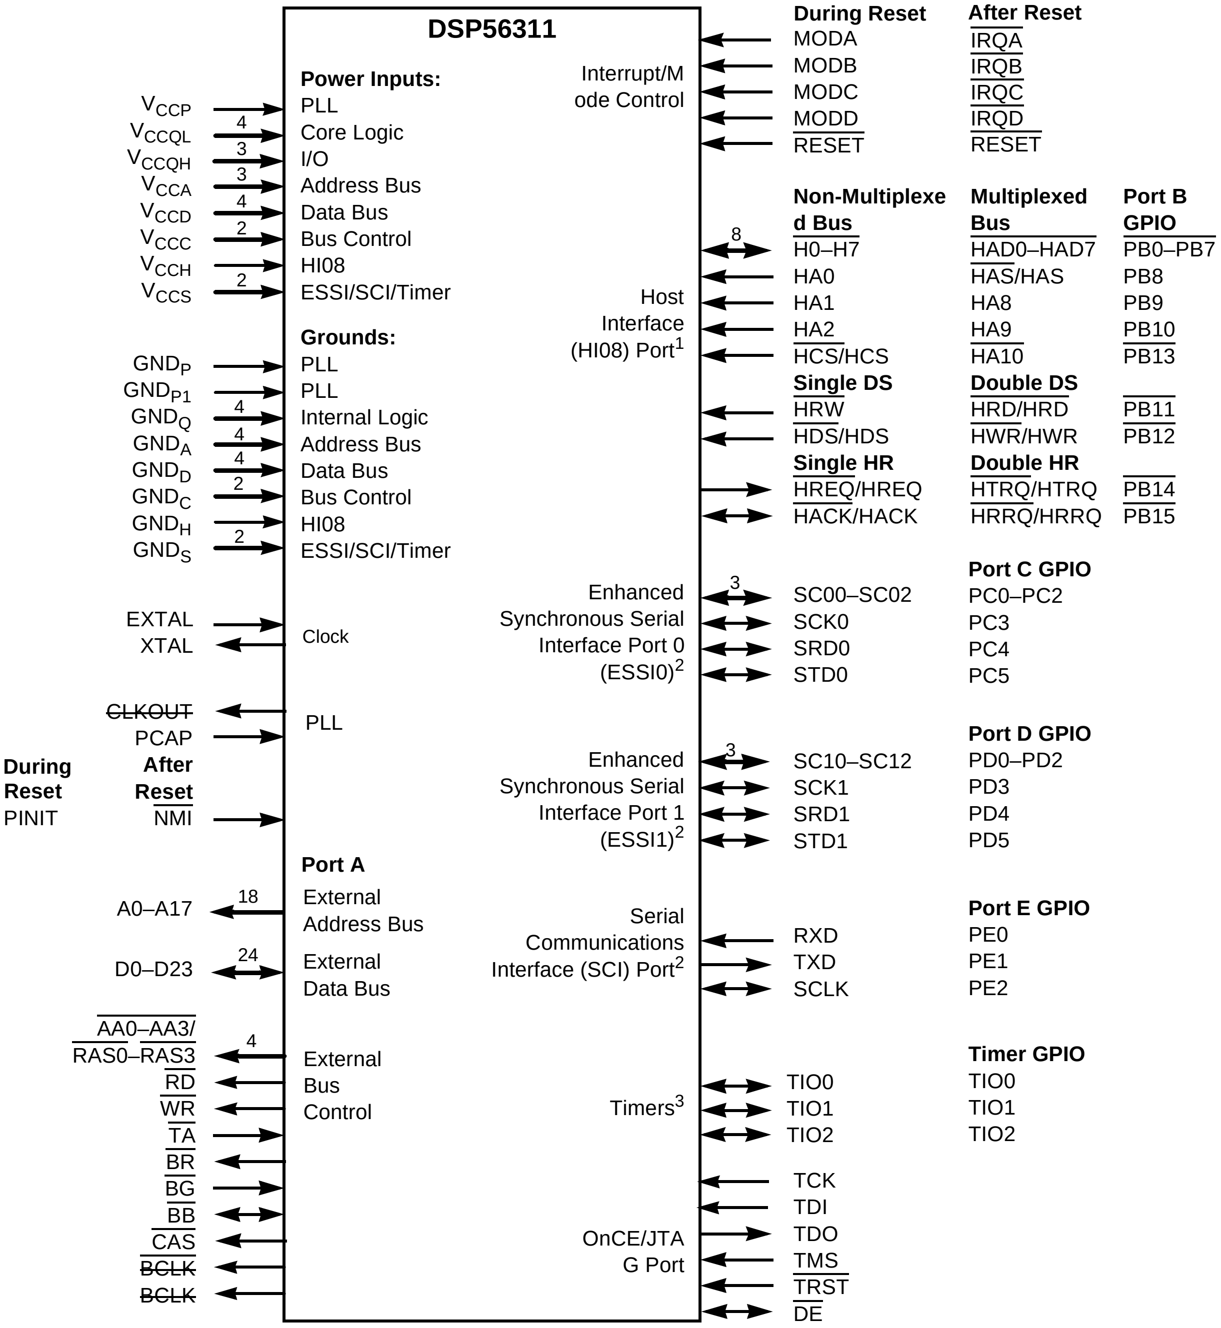
The DSP56311 input and output signals are organized into functional groups as shown in **Table 1-1.** **Figure 1-1.** diagrams the DSP56311 signals by functional group. The remainder of this chapter describes the signal pins in each functional group.

Table 1-1. DSP56311 Functional Signal Groupings

Functional Group		Number of Signals
Power (V_{CC})		20
Ground (GND)		19
Clock		2
PLL		3
Address bus	Port A[1]	18
Data bus		24
Bus control		13
Interrupt and mode control		5
Host interface (HI08)	Port B[2]	16
Enhanced synchronous serial interface (ESSI)	Ports C and D[3]	12
Serial communication interface (SCI)	Port E[4]	3
Timer		3
OnCE/JTAG Port		6

Notes:
1. Port A signals define the external memory interface port, including the external address bus, data bus, and control signals.
2. Port B signals are the HI08 port signals multiplexed with the GPIO signals.
3. Port C and D signals are the two ESSI port signals multiplexed with the GPIO signals.
4. Port E signals are the SCI port signals multiplexed with the GPIO signals.

Note: The Clock Output (CLKOUT) is not functional in the DSP56311. The CLKOUT output pin provides a 50 percent duty cycle output clock synchronized to the internal processor clock when the Phase Lock Loop (PLL) is enabled and locked. At 150 MHz and above, CLKOUT produces a low-amplitude waveform that is not usable externally by other devices. Several alternatives to using CLKOUT exist, such as enabling bus arbitration by setting the Asynchronous Bus Arbitration Enable BIt (ABE) in the Operating Mode register. When set, the ABE bit eliminates the setup and hold time requirements with respect to CLKOUT for $\overline{\text{BB}}$ and $\overline{\text{BG}}$.



Note:
1. The HI08 port supports a non-multiplexed or a multiplexed bus, single or double Data Strobe (DS), and single or double Host Request (HR) configurations. Since each of these modes is configured independently, any combination of these modes is possible. These HI08 signals can also be configured alternately as GPIO signals (PB0–PB15). Signals with dual designations (for example, HAS/HAS) have configurable polarity.
2. The ESSI0, ESSI1, and SCI signals are multiplexed with the Port C GPIO signals (PC0–PC5), Port D GPIO signals (PD0–PD5), and Port E GPIO signals (PE0–PE2), respectively.
3. TIO0–TIO2 can be configured as GPIO signals.

Figure 1-1. Signals Identified by Functional Group

POWER

Table 1-2. Power Inputs

Power Name	Description
V_{CCP}	**PLL Power**—V_{CCP} is V_{CC} dedicated for PLL use. The voltage should be well-regulated and the input should be provided with an extremely low impedance path to the V_{CC} power rail.
V_{CCQL}	**Quiet Core (Low) Power**—V_{CCQL} is an isolated power for the core processing logic. This input must be isolated externally from all other chip power inputs. The user must provide adequate external decoupling capacitors.
V_{CCQH}	**Quiet External (High) Power**—V_{CCQH} is a quiet power source for I/O lines. This input must be tied externally to all other chip power inputs, *except* V_{CCQL}. The user must provide adequate decoupling capacitors.
V_{CCA}	**Address Bus Power**—V_{CCA} is an isolated power for sections of the address bus I/O drivers. This input must be tied externally to all other chip power inputs, *except* V_{CCQL}. The user must provide adequate external decoupling capacitors.
V_{CCD}	**Data Bus Power**—V_{CCD} is an isolated power for sections of the data bus I/O drivers. This input must be tied externally to all other chip power inputs, *except* V_{CCQL}. The user must provide adequate external decoupling capacitors.
V_{CCC}	**Bus Control Power**—V_{CCC} is an isolated power for the bus control I/O drivers. This input must be tied externally to all other chip power inputs**,** *except* V_{CCQL}. The user must provide adequate external decoupling capacitors.
V_{CCH}	**Host Power**—V_{CCH} is an isolated power for the HI08 I/O drivers. This input must be tied externally to all other chip power inputs**,** *except* V_{CCQL}. The user must provide adequate external decoupling capacitors.
V_{CCS}	**ESSI, SCI, and Timer Power**—V_{CCS} is an isolated power for the ESSI, SCI, and timer I/O drivers. This input must be tied externally to all other chip power inputs, *except* V_{CCQL}. The user must provide adequate external decoupling capacitors.

GROUND

Table 1-3. Grounds

Ground Name	Description
GND_P	**PLL Ground**—GND_P is ground-dedicated for PLL use. The connection should be provided with an extremely low-impedance path to ground. V_{CCP} should be bypassed to GND_P by a 0.47 mF capacitor located as close as possible to the chip package.

Table 1-3. Grounds

Ground Name	Description
GND_{P1}	**PLL Ground 1**—GND_{P1} is ground-dedicated for PLL use. The connection should be provided with an extremely low-impedance path to ground.
GND_Q	**Quiet Ground**—GND_Q is an isolated ground for the internal processing logic. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors.
GND_A	**Address Bus Ground**—GND_A is an isolated ground for sections of the address bus I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors. There are four GND_A connections.
GND_D	**Data Bus Ground**—GND_D is an isolated ground for sections of the data bus I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors.
GND_C	**Bus Control Ground**—GND_C is an isolated ground for the bus control I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors.
GND_H	**Host Ground**—GND_H is an isolated ground for the HI08 I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors.
GND_S	**ESSI, SCI, and Timer Ground**—GND_S is an isolated ground for the ESSI, SCI, and timer I/O drivers. This connection must be tied externally to all other chip ground connections. The user must provide adequate external decoupling capacitors.

CLOCK

Table 1-4. Clock Signals

Signal Name	Type	State During Reset	Signal Description
EXTAL	Input	Input	**External Clock/Crystal Input**—EXTAL interfaces the internal crystal oscillator input to an external crystal or an external clock.
XTAL	Output	Chip-driven	**Crystal Output**—XTAL connects the internal crystal oscillator output to an external crystal. If an external clock is used, leave XTAL unconnected.

PLL

Table 1-5. Phase-Locked Loop Signals

Signal Name	Type	State During Reset	Signal Description
PCAP	Input	Input	**PLL Capacitor**—PCAP is an input connecting an off-chip capacitor to the PLL filter. Connect one capacitor terminal to PCAP and the other terminal to V_{CCP}. If the PLL is not used, PCAP may be tied to V_{CC}, GND, or left floating.
~~CLKOUT~~	~~Output~~	~~Chip-driven~~	At speeds made possible by HiP4 process technology, CLKOUT produces a low-amplitude waveform that is not usable externally by other devices. Alternatives to using CLKOUT exist. One example is the use of the Asynchronous Bus Arbitration Enable Bit (ABE) in the Operating Mode register. When set, the ABE bit eliminates the setup and hold time requirements with respect to CLKOUT for $\overline{BB}$ and $\overline{BG}$. Future changes in process technology may continue to produce alternatives to CLKOUT.
PINIT $\overline{NMI}$	Input Input	Input	**PLL Initial**—During assertion of $\overline{RESET}$, the value of PINIT is written into the PLL enable (PEN) bit of the PLL control (PCTL) register, determining whether the PLL is enabled or disabled. **Nonmaskable Interrupt**—After $\overline{RESET}$ deassertion and during normal instruction processing, this Schmitt-trigger input is the negative-edge-triggered NMI request internally synchronized to CLKOUT.

EXTERNAL MEMORY EXPANSION PORT (PORT A)

Note: When the DSP56311 enters a low-power standby mode (stop or wait), it releases bus mastership and tri-states the relevant Port A signals: A0–A17, D0–D23, AA0/$\overline{RAS0}$–AA3/$\overline{RAS3}$, $\overline{RD}$, $\overline{WR}$, $\overline{BB}$, $\overline{CAS}$, BCLK, $\overline{BCLK}$.

External Address Bus

Table 1-6. External Address Bus Signals

Signal Name	Type	State During Reset	Signal Description
A0–A17	Output	Tri-stated	**Address Bus**—When the DSP is the bus master, A0–A17 are active-high outputs that specify the address for external program and data memory accesses. Otherwise, the signals are tri-stated. To minimize power dissipation, A0–A17 do not change state when external memory spaces are not being accessed.

External Data Bus

Table 1-7. External Data Bus Signals

Signal Name	Type	State During Reset	Signal Description
D0–D23	Input/ Output	Tri-stated	**Data Bus**—When the DSP is the bus master, D0–D23 are active-high, bidirectional input/outputs that provide the bidirectional data bus for external program and data memory accesses. Otherwise, D0–D23 are tri-stated. These lines have weak keepers to maintain the last state even if all drivers are tri-stated.

External Bus Control

Table 1-8. External Bus Control Signals

Signal Name	Type	State During Reset	Signal Description
AA0–AA3 $\overline{\text{RAS0}}$–$\overline{\text{RAS3}}$	Output Output	Tri-stated	**Address Attribute**—When defined as AA, these signals can be used as chip selects or additional address lines. The default use defines a priority scheme under which only one AA signal can be asserted at a time. Setting the AA priority disable (APD) bit (Bit 14) of the OMR, the priority mechanism is disabled and the lines can be used together as four external lines that can be decoded externally into 16 chip select signals. **Row Address Strobe**—When defined as $\overline{\text{RAS}}$, these signals can be used as $\overline{\text{RAS}}$ for DRAM interface. These signals are tri-statable outputs with programmable polarity.
$\overline{\text{RD}}$	Output	Tri-stated	**Read Enable**—When the DSP is the bus master, $\overline{\text{RD}}$ is an active-low output that is asserted to read external memory on the data bus (D0–D23). Otherwise, $\overline{\text{RD}}$ is tri-stated.
$\overline{\text{WR}}$	Output	Tri-stated	**Write Enable**—When the DSP is the bus master, $\overline{\text{WR}}$ is an active-low output that is asserted to write external memory on the data bus (D0–D23). Otherwise, the signals are tri-stated.
$\overline{\text{TA}}$	Input	Ignored Input	**Transfer Acknowledge**—If the DSP56311 is the bus master and there is no external bus activity, or the DSP56311 is not the bus master, the $\overline{\text{TA}}$ input is ignored. The $\overline{\text{TA}}$ input is a data transfer acknowledge (DTACK) function that can extend an external bus cycle indefinitely. Any number of wait states (1, 2. . .infinity) may be added to the wait states inserted by the bus control register (BCR) by keeping $\overline{\text{TA}}$ deasserted. In typical operation, $\overline{\text{TA}}$ is deasserted at the start of a bus cycle, is asserted to enable completion of the bus cycle, and is deasserted before the next bus cycle. The current bus cycle completes one clock period after $\overline{\text{TA}}$ is asserted synchronous to CLKOUT. The number of wait states is determined by the $\overline{\text{TA}}$ input or by the BCR, whichever is longer. The BCR can be used to set the minimum number of wait states in external bus cycles. In order to use the $\overline{\text{TA}}$ functionality, the BCR must be programmed to at least one wait state. A zero wait state access cannot be extended by $\overline{\text{TA}}$ deassertion; otherwise, improper operation may result. $\overline{\text{TA}}$ can operate synchronously or asynchronously depending on the setting of the TAS bit in the OMR. $\overline{\text{TA}}$ functionality may not be used while performing DRAM type accesses; otherwise, improper operation may result.

Table 1-8. External Bus Control Signals (Continued)

Signal Name	Type	State During Reset	Signal Description
$\overline{\text{BR}}$	Output	Output (deasserted)	**Bus Request**—$\overline{\text{BR}}$ is an active-low output, never tri-stated. $\overline{\text{BR}}$ is asserted when the DSP requests bus mastership. $\overline{\text{BR}}$ is deasserted when the DSP no longer needs the bus. $\overline{\text{BR}}$ may be asserted or deasserted independently of whether the DSP56311 is a bus master or a bus slave. Bus “parking” allows $\overline{\text{BR}}$ to be deasserted even though the DSP56311 is the bus master. (See the description of bus “parking” in the $\overline{\text{BB}}$ signal description.) The bus request hole (BRH) bit in the BCR allows $\overline{\text{BR}}$ to be asserted under software control even though the DSP does not need the bus. $\overline{\text{BR}}$ is typically sent to an external bus arbitrator that controls the priority, parking, and tenure of each master on the same external bus. $\overline{\text{BR}}$ is only affected by DSP requests for the external bus, never for the internal bus. During hardware reset, $\overline{\text{BR}}$ is deasserted and the arbitration is reset to the bus slave state.
$\overline{\text{BG}}$	Input	Ignored Input	**Bus Grant**—$\overline{\text{BG}}$ is an active-low input. ~~$\overline{\text{BG}}$ must be asserted/deasserted synchronous to CLKOUT for proper operation.~~ $\overline{\text{BG}}$ is asserted by an external bus arbitration circuit when the DSP56311 becomes the next bus master. When $\overline{\text{BG}}$ is asserted, the DSP56311 must wait until $\overline{\text{BB}}$ is deasserted before taking bus mastership. When $\overline{\text{BG}}$ is deasserted, bus mastership is typically given up at the end of the current bus cycle. This may occur in the middle of an instruction that requires more than one external bus cycle for execution. The default operation of this bit requires a setup and hold time as specified in *DSP56311 Technical Data* (the data sheet). An alternate mode can be invoked: set the asynchronous bus arbitration enable (ABE) bit (Bit 13) in the OMR. When this bit is set, $\overline{\text{BG}}$ and $\overline{\text{BB}}$ are synchronized internally. This eliminates the respective setup and hold time requirements but adds a required delay between the deassertion of an initial $\overline{\text{BG}}$ input and the assertion of a subsequent $\overline{\text{BG}}$ input.

Table 1-8. External Bus Control Signals (Continued)

Signal Name	Type	State During Reset	Signal Description
$\overline{BB}$	Input/Output	Input	**Bus Busy**—$\overline{BB}$ is a bidirectional active-low input/output ~~and must be asserted and deasserted synchronous to CLKOUT~~.$\overline{BB}$ indicates that the bus is active. Only after $\overline{BB}$ is deasserted can the pending bus master become the bus master (and then assert the signal again). The bus master may keep $\overline{BB}$ asserted after ceasing bus activity regardless of whether $\overline{BR}$ is asserted or deasserted. Called "bus parking," this allows the current bus master to reuse the bus without rearbitration until another device requires the bus. The deassertion of $\overline{BB}$ is done by an "active pull-up" method (that is, $\overline{BB}$ is driven high and then released and held high by an external pull-up resistor). The default operation of this bit requires a setup and hold time as specified in the *DSP56311 Technical Data sheet*. An alternate mode can be invoked: set the ABE bit (Bit 13) in the OMR. When this bit is set, $\overline{BG}$ and $\overline{BB}$ are synchronized internally. See $\overline{BG}$ for additional information. $\overline{BB}$ requires an external pull-up resistor.
$\overline{CAS}$	Output	Tri-stated	**Column Address Strobe**—When the DSP is the bus master, $\overline{CAS}$ is an active-low output used by DRAM to strobe the column address. Otherwise, if the bus mastership enable (BME) bit in the DRAM control register is cleared, the signal is tri-stated.
~~BCLK~~	~~Output~~	~~Tri-stated~~	**Bus Clock**—With the application of HiP4 process technology, BCLK does not function. Without BCLK functioning, no signal exists to initiate the sampling process, and the DSP does not output any addresses. Therefore, Address Trace mode is not supported under the HiP4 process.
~~$\overline{BCLK}$~~	~~Output~~	~~Tri-stated~~	~~**Bus Clock Not**—When the DSP is the bus master, $\overline{BCLK}$ is an active-low output and is the inverse of the BCLK signal. Otherwise, the signal is tri-stated.~~

INTERRUPT AND MODE CONTROL

The interrupt and mode control signals select the chip's operating mode as it comes out of hardware reset. After $\overline{RESET}$ is deasserted, these inputs are hardware interrupt request lines.

Table 1-9. Interrupt and Mode Control

Signal Name	Type	State During Reset	Signal Description
RESET	Input	Input	**Reset**—RESET is an active-low, Schmitt-trigger input. ~~Deassertion of RESET is internally synchronized to CLKOUT~~. When asserted, the chip is placed in the Reset state and the internal phase generator is reset. The Schmitt-trigger input allows a slowly rising input (such as a capacitor charging) to reset the chip reliably. ~~If RESET is deasserted synchronous to CLKOUT, exact start-up timing is guaranteed, allowing multiple processors to start synchronously and operate together in “lock-step.”~~ When the RESET signal is deasserted, the initial chip operating mode is latched from the MODA, MODB, MODC, and MODD inputs. The RESET signal must be asserted after power up.
MODA IRQA	Input Input	Input	**Mode Select A**—MODA is an active-low Schmitt-trigger input~~,~~ ~~internally synchronized to CLKOUT~~. MODA, MODB, MODC, and MODD select one of 16 initial chip operating modes, latched into the OMR when the RESET signal is deasserted. **External Interrupt Request A**—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. ~~If IRQA is asserted synchronous to CLKOUT, multiple processors can be resynchronized using the WAIT instruction and asserting IRQA to exit the wait state.~~ If the processor is in the stop standby state and IRQA is asserted, the processor will exit the stop state.
MODB IRQB	Input Input	Input	**Mode Select B**—MODB is an active-low Schmitt-trigger input~~,~~ ~~internally synchronized to CLKOUT~~. MODA, MODB, MODC, and MODD select one of 16 initial chip operating modes, latched into the OMR when the RESET signal is deasserted. **External Interrupt Request B**—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. ~~If IRQB is asserted synchronous to CLKOUT, multiple processors can be resynchronized using the WAIT instruction and asserting IRQB to exit the wait state.~~ If the processor is in the stop standby state and IRQB is asserted, the processor will exit the stop state.
MODC IRQC	Input Input	Input	**Mode Select C**—MODC is an active-low Schmitt-trigger input~~,~~ ~~internally synchronized to CLKOUT~~. MODA, MODB, MODC, and MODD select one of 16 initial chip operating modes, latched into the OMR when the RESET signal is deasserted. **External Interrupt Request C**—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. ~~If IRQC is asserted synchronous to CLKOUT, multiple processors can be resynchronized using the WAIT instruction and asserting IRQC to exit the wait state.~~ If the processor is in the stop standby state and IRQC is asserted, the processor will exit the stop state.

Table 1-9. Interrupt and Mode Control (Continued)

Signal Name	Type	State During Reset	Signal Description
MODD	Input	Input	**Mode Select D**—MODD is an active-low Schmitt-trigger input~~, internally synchronized to CLKOUT~~. MODA, MODB, MODC, and MODD select one of 16 initial chip operating modes, latched into the OMR when the $\overline{\text{RESET}}$ signal is deasserted.
$\overline{\text{IRQD}}$	Input		**External Interrupt Request D**—After reset, this input becomes a level-sensitive or negative-edge-triggered, maskable interrupt request input during normal instruction processing. ~~If $\overline{\text{IRQD}}$ is asserted synchronous to CLKOUT, multiple processors can be resynchronized using the WAIT instruction and asserting $\overline{\text{IRQD}}$ to exit the wait state.~~ If the processor is in the stop standby state and $\overline{\text{IRQD}}$ is asserted, the processor will exit the stop state.

HI08

The HI08 provides a fast, 8-bit, parallel data port that may be connected directly to the host bus. The HI08 supports a variety of standard buses and can be directly connected to a number of industry standard microcomputers, microprocessors, DSPs, and DMA hardware.

Table 1-10. Host Interface

Signal Name	Type	State During Reset	Signal Description
H0–H7	Input/ Output	Tri-stated	**Host Data**—When the HI08 is programmed to interface a nonmultiplexed host bus and the host interface (HI) function is selected, these signals are lines 0–7 of the data bidirectional, tri-state bus.
HAD0–HAD7	Input/ Output		**Host Address—**When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, these signals are lines 0–7 of the address/data bidirectional, multiplexed, tri-state bus.
PB0–PB7	Input or Output		**Port B 0–7**—When the HI08 is configured as GPIO through the host port control register (HPCR), these signals are individually programmed as inputs or outputs through the HI08 data direction register (HDDR). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
HA0	Input	Input	**Host Address Input 0**—When the HI08 is programmed to interface a nonmultiplexed host bus and the HI function is selected, this signal is line 0 of the host address input bus.
$\overline{HAS}$/HAS	Input		**Host Address Strobe—**When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is the host address strobe (HAS) Schmitt-trigger input. The polarity of the address strobe is programmable but is configured active-low ($\overline{HAS}$) following reset.
PB8	Input or Output		**Port B 8**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

Table 1-10. Host Interface (Continued)

Signal Name	Type	State During Reset	Signal Description
HA1	Input	Input	**Host Address Input 1**—When the HI08 is programmed to interface a nonmultiplexed host bus and the HI function is selected, this signal is line 1 of the host address (HA1) input bus.
HA8	Input		**Host Address 8**—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 8 of the host address (HA8) input bus.
PB9	Input or Output		**Port B 9**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
HA2	Input	Input	**Host Address Input 2**—When the HI08 is programmed to interface a nonmultiplexed host bus and the HI function is selected, this signal is line 2 of the host address (HA2) input bus.
HA9	Input		**Host Address 9**—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 9 of the host address (HA9) input bus.
PB10	Input or Output		**Port B 10**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
HRW	Input	Input	**Host Read/Write**—When HI08 is programmed to interface a single-data-strobe host bus and the HI function is selected, this signal is the Host Read/$\overline{\text{Write}}$ (HRW) input.
$\overline{\text{HRD}}$/HRD	Input		**Host Read Data**—When HI08 is programmed to interface a double-data-strobe host bus and the HI function is selected, this signal is the HRD strobe Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low ($\overline{\text{HRD}}$) after reset.
PB11	Input or Output		**Port B 11**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

Table 1-10. Host Interface (Continued)

Signal Name	Type	State During Reset	Signal Description
$\overline{\mathrm{HDS}}$/HDS	Input	Input	**Host Data Strobe**—When HI08 is programmed to interface a single-data-strobe host bus and the HI function is selected, this signal is the host data strobe (HDS) Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low ($\overline{\mathrm{HDS}}$) following reset.
$\overline{\mathrm{HWR}}$/HWR	Input		**Host Write Data**—When HI08 is programmed to interface a double-data-strobe host bus and the HI function is selected, this signal is the host write data strobe (HWR) Schmitt-trigger input. The polarity of the data strobe is programmable, but is configured as active-low ($\overline{\mathrm{HWR}}$) following reset.
PB12	Input or Output		**Port B 12**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
HCS	Input	Input	**Host Chip Select**—When HI08 is programmed to interface a nonmultiplexed host bus and the HI function is selected, this signal is the host chip select (HCS) input. The polarity of the chip select is programmable, but is configured active-low ($\overline{\mathrm{HCS}}$) after reset.
HA10	Input		**Host Address 10**—When HI08 is programmed to interface a multiplexed host bus and the HI function is selected, this signal is line 10 of the host address (HA10) input bus.
PB13	Input or Output		**Port B 13**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

Table 1-10. Host Interface (Continued)

Signal Name	Type	State During Reset	Signal Description
$\overline{\text{HREQ}}$/HREQ	Output	Input	**Host Request**—When HI08 is programmed to interface a single host request host bus and the HI function is selected, this signal is the host request (HREQ) output. The polarity of the host request is programmable, but is configured as active-low ($\overline{\text{HREQ}}$) following reset. The host request may be programmed as a driven or open-drain output.
$\overline{\text{HTRQ}}$/HTRQ	Output		**Transmit Host Request**—When HI08 is programmed to interface a double host request host bus and the HI function is selected, this signal is the transmit host request (HTRQ) output. The polarity of the host request is programmable, but is configured as active-low ($\overline{\text{HTRQ}}$) following reset. The host request may be programmed as a driven or open-drain output.
PB14	Input or Output		**Port B 14**—When the HI08 is programmed to interface a multiplexed host bus and the signal is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
$\overline{\text{HACK}}$/ HACK	Input	Input	**Host Acknowledge**—When HI08 is programmed to interface a single host request host bus and the HI function is selected, this signal is the host acknowledge (HACK) Schmitt-trigger input. The polarity of the host acknowledge is programmable, but is configured as active-low ($\overline{\text{HACK}}$) after reset.
$\overline{\text{HRRQ}}$/ HRRQ	Output		**Receive Host Request**—When HI08 is programmed to interface a double host request host bus and the HI function is selected, this signal is the receive host request (HRRQ) output. The polarity of the host request is programmable, but is configured as active-low ($\overline{\text{HRRQ}}$) after reset. The host request may be programmed as a driven or open-drain output.
PB15	Input or Output		**Port B 15**—When the HI08 is configured as GPIO through the HPCR, this signal is individually programmed as an input or output through the HDDR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

ENHANCED SYNCHRONOUS SERIAL INTERFACE 0

There are two synchronous serial interfaces (ESSI0 and ESSI1) that provide a full-duplex serial port for serial communication with a variety of serial devices, including one or more industry-standard codecs, other DSPs, microprocessors, and peripherals which implement the Motorola serial peripheral interface (SPI).

Table 1-11. Enhanced Synchronous Serial Interface 0

Signal Name	Type	State During Reset	Signal Description
SC00 PC0	Input or Output	Input	**Serial Control 0**—The function of SC00 is determined by the selection of either synchronous or asynchronous mode. For asynchronous mode, this signal will be used for the receive clock I/O (Schmitt-trigger input). For synchronous mode, this signal is used either for transmitter 1 output or for serial I/O flag 0. **Port C 0**—The default configuration following reset is GPIO input PC0. When configured as PC0, signal direction is controlled through the port directions register (PRR0). The signal can be configured as ESSI signal SC00 through the port control register (PCR0). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SC01 PC1	Input/ Output Input or Output	Input	**Serial Control 1**—The function of this signal is determined by the selection of either synchronous or asynchronous mode. For asynchronous mode, this signal is the receiver frame sync I/O. For synchronous mode, this signal is used either for transmitter 2 output or for serial I/O flag 1. **Port C 1**—The default configuration following reset is GPIO input PC1. When configured as PC1, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SC01 through PCR0. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SC02 PC2	Input/ Output Input or Output	Input	**Serial Control Signal 2**—SC02 is used for frame sync I/O. SC02 is the frame sync for both the transmitter and receiver in synchronous mode, and for the transmitter only in asynchronous mode. When configured as an output, this signal is the internally generated frame sync signal. When configured as an input, this signal receives an external frame sync signal for the transmitter (and the receiver in synchronous operation). **Port C 2**—The default configuration following reset is GPIO input PC2. When configured as PC2, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SC02 through PCR0. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

Table 1-11. Enhanced Synchronous Serial Interface 0 (Continued)

Signal Name	Type	State During Reset	Signal Description
SCK0	Input/ Output	Input	**Serial Clock**—SCK0 is a bidirectional Schmitt-trigger input signal providing the serial bit rate clock for the ESSI. The SCK0 is a clock input or output, used by both the transmitter and receiver in synchronous modes or by the transmitter in asynchronous modes. Although an external serial clock can be independent of and asynchronous to the DSP system clock, it must exceed the minimum clock cycle time of 6T (that is, the system clock frequency must be at least three times the external ESSI clock frequency). The ESSI needs at least three DSP phases inside each half of the serial clock.
PC3	Input or Output		**Port C 3**—The default configuration following reset is GPIO input PC3. When configured as PC3, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SCK0 through PCR0. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SRD0	Input/ Output	Input	**Serial Receive Data**—SRD0 receives serial data and transfers the data to the ESSI receive shift register. SRD0 is an input when data is being received.
PC4	Input or Output		**Port C 4**—The default configuration following reset is GPIO input PC4. When configured as PC4, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal SRD0 through PCR0. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
STD0	Input/ Output	Input	**Serial Transmit Data**—STD0 is used for transmitting data from the serial transmit shift register. STD0 is an output when data is being transmitted.
PC5	Input or Output		**Port C 5**—The default configuration following reset is GPIO input PC5. When configured as PC5, signal direction is controlled through PRR0. The signal can be configured as an ESSI signal STD0 through PCR0. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

ENHANCED SYNCHRONOUS SERIAL INTERFACE 1

Table 1-12. Enhanced Serial Synchronous Interface 1

Signal Name	Type	State During Reset	Signal Description
SC10 PD0	Input or Output Input or Output	Input	**Serial Control 0**—The function of SC10 is determined by the selection of either synchronous or asynchronous mode. For asynchronous mode, this signal will be used for the receive clock I/O (Schmitt-trigger input). For synchronous mode, this signal is used either for transmitter 1 output or for serial I/O flag 0. **Port D 0**—The default configuration following reset is GPIO input PD0. When configured as PD0, signal direction is controlled through the port directions register (PRR1). The signal can be configured as an ESSI signal SC10 through the port control register (PCR1). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SC11 PD1	Input/ Output Input or Output	Input	**Serial Control 1**—The function of this signal is determined by the selection of either synchronous or asynchronous mode. For asynchronous mode, this signal is the receiver frame sync I/O. For synchronous mode, this signal is used either for Transmitter 2 output or for Serial I/O Flag 1. **Port D 1**—The default configuration following reset is GPIO input PD1. When configured as PD1, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SC11 through PCR1. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SC12 PD2	Input/ Output Input or Output	Input	**Serial Control Signal 2**—SC12 is used for frame sync I/O. SC12 is the frame sync for both the transmitter and receiver in synchronous mode, and for the transmitter only in asynchronous mode. When configured as an output, this signal is the internally generated frame sync signal. When configured as an input, this signal receives an external frame sync signal for the transmitter (and the receiver in synchronous operation). **Port D 2**—The default configuration following reset is GPIO input PD2. When configured as PD2, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SC12 through PCR1. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

Table 1-12. Enhanced Serial Synchronous Interface 1 (Continued)

Signal Name	Type	State During Reset	Signal Description
SCK1	Input/ Output	Input	**Serial Clock**—SCK1 is a bidirectional Schmitt-trigger input signal providing the serial bit rate clock for the ESSI. The SCK1 is a clock input or output used by both the transmitter and receiver in synchronous modes, or by the transmitter in asynchronous modes. Although an external serial clock can be independent of and asynchronous to the DSP system clock, it must exceed the minimum clock cycle time of 6T (that is, the system clock frequency must be at least three times the external ESSI clock frequency). The ESSI needs at least three DSP phases inside each half of the serial clock.
PD3	Input or Output		**Port D 3**—The default configuration following reset is GPIO input PD3. When configured as PD3, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SCK1 through PCR1. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SRD1	Input/ Output	Input	**Serial Receive Data**—SRD1 receives serial data and transfers the data to the ESSI receive shift register. SRD1 is an input when data is being received.
PD4	Input or Output		**Port D 4**—The default configuration following reset is GPIO input PD4. When configured as PD4, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal SRD1 through PCR1. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
STD1	Input/ Output	Input	**Serial Transmit Data**—STD1 is used for transmitting data from the serial transmit shift register. STD1 is an output when data is being transmitted.
PD5	Input or Output		**Port D 5**—The default configuration following reset is GPIO input PD5. When configured as PD5, signal direction is controlled through PRR1. The signal can be configured as an ESSI signal STD1 through PCR1. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

SCI

The SCI provides a full duplex port for serial communication to other DSPs, microprocessors, or peripherals such as modems.

Table 1-13. Serial Communication Interface

Signal Name	Type	State During Reset	Signal Description
RXD PE0	Input Input or Output	Input	**Serial Receive Data**—This input receives byte oriented serial data and transfers it to the SCI receive shift register. **Port E 0**—The default configuration following reset is GPIO input PE0. When configured as PE0, signal direction is controlled through the SCI port directions register (PRR). The signal can be configured as an SCI signal RXD through the SCI port control register (PCR). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
TXD PE1	Output Input or Output	Input	**Serial Transmit Data**—This signal transmits data from SCI transmit data register. **Port E 1**—The default configuration following reset is GPIO input PE1. When configured as PE1, signal direction is controlled through the SCI PRR. The signal can be configured as an SCI signal TXD through the SCI PCR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
SCLK PE2	Input/ Output Input or Output	Input	**Serial Clock**—This is the bidirectional Schmitt-trigger input signal providing the input or output clock used by the transmitter and/or the receiver. **Port E 2**—The default configuration following reset is GPIO input PE2. When configured as PE2, signal direction is controlled through the SCI PRR. The signal can be configured as an SCI signal SCLK through the SCI PCR. Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

TIMERS

Three identical and independent timers are implemented in the DSP56311. Each timer can use internal or external clocking and can either interrupt the DSP56311 after a specified number of events (clocks) or signal an external device after counting a specific number of internal events.

Table 1-14. Triple Timer Signals

Signal Name	Type	State During Reset	Signal Description
TIO0	Input or Output	Input	**Timer 0 Schmitt-Trigger Input/Output**— When Timer 0 functions as an external event counter or in measurement mode, TIO0 is used as input. When Timer 0 functions in watchdog, timer, or pulse modulation mode, TIO0 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a timer I/O through the timer 0 control/status register (TCSR0). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
TIO1	Input or Output	Input	**Timer 1 Schmitt-Trigger Input/Output**— When Timer 1 functions as an external event counter or in measurement mode, TIO1 is used as input. When Timer 1 functions in watchdog, timer, or pulse modulation mode, TIO1 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a timer I/O through the timer 1 control/status register (TCSR1). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.
TIO2	Input or Output	Input	**Timer 2 Schmitt-Trigger Input/Output**— When Timer 2 functions as an external event counter or in measurement mode, TIO2 is used as input. When Timer 2 functions in watchdog, timer, or pulse modulation mode, TIO2 is used as output. The default mode after reset is GPIO input. This can be changed to output or configured as a timer I/O through the timer 2 control/status register (TCSR2). Note: This signal has a weak keeper to maintain the last state even if all drivers are tri-stated.

JTAG AND OnCE INTERFACE

The DSP56300 family and in particular the DSP56311 support circuit-board test strategies based on the *IEEE 1149.1 Standard Test Access Port and Boundary Scan Architecture*, the industry standard developed under the sponsorship of the Test Technology Committee of IEEE and the JTAG.

The OnCE module provides a means to interface nonintrusively with the DSP56300 core and its peripherals so that you can examine registers, memory, or on-chip peripherals. Functions of the OnCE module are provided through the JTAG TAP signals.

For programming models, see the chapter on debugging support in the *DSP56300 Family Manual*.

Table 1-15. OnCE/JTAG Interface

Signal Name	Type	State During Reset	Signal Description
TCK	Input	Input	**Test Clock**—TCK is a test clock input signal used to synchronize the JTAG test logic.
TDI	Input	Input	**Test Data Input**—TDI is a test data serial input signal used for test instructions and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TDO	Output	Tri-stated	**Test Data Output**—TDO is a test data serial output signal used for test instructions and data. TDO is tri-statable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TMS	Input	Input	**Test Mode Select**—TMS is an input signal used to sequence the test controller’s state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
$\overline{\text{TRST}}$	Input	Input	**Test Reset**—$\overline{\text{TRST}}$ is an active-low Schmitt-trigger input signal used to asynchronously initialize the test controller. $\overline{\text{TRST}}$ has an internal pull-up resistor. $\overline{\text{TRST}}$ must be asserted after power up.

Table 1-15. OnCE/JTAG Interface (Continued)

Signal Name	Type	State During Reset	Signal Description
$\overline{\text{DE}}$	Input/ Output	Input	**Debug Event**—$\overline{\text{DE}}$ is an open-drain, bidirectional, active-low signal that provides, as an input, a means of entering the debug mode of operation from an external command controller, and, as an output, a means of acknowledging that the chip has entered the debug mode. This signal, when asserted as an input, causes the DSP56300 core to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for commands to be entered from the debug serial input line. This signal is asserted as an output for three clock cycles when the chip enters the debug mode as a result of a debug request or as a result of meeting a breakpoint condition. The $\overline{\text{DE}}$ has an internal pull-up resistor. This is not a standard part of the JTAG TAP controller. The signal connects directly to the OnCE module to initiate debug mode directly or to provide a direct external indication that the chip has entered the debug mode. All other interface with the OnCE module must occur through the JTAG port.

SECTION 2

SPECIFICATIONS

INTRODUCTION

The DSP56311 is fabricated in high density CMOS with Transistor-Transistor Logic (TTL) compatible inputs and outputs. The DSP56311 specifications are preliminary and are from design simulations, and may not be fully tested or guaranteed. Finalized specifications will be published after full characterization and device qualifications are complete.

MAXIMUM RATINGS

CAUTION

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, normal precautions should be taken to avoid exceeding maximum voltage ratings. Reliability is enhanced if unused inputs are tied to an appropriate logic voltage level (for example, either GND or V_{CC}).

Note: In the calculation of timing requirements, adding a maximum value of one specification to a minimum value of another specification does not yield a reasonable sum. A maximum specification is calculated using a worst case variation of process parameter values in one direction. The minimum specification is calculated using the worst case for the same parameters in the opposite direction. Therefore, a “maximum” value for a specification never occurs in the same device that has a “minimum” value for another specification; adding a maximum to a minimum represents a condition that can never exist.

Table 2-1. Maximum Ratings

Note: 1. Rating[1]	Symbol	Value[1, 2]	Unit
Supply Voltage	V_{CC}	-0.1 to 2.0	V
Input/Output Supply Voltage	V_{CCH}	-0.3 to 4	V
All input voltages	V_{IN}	GND - 0.3 to V_{CCH} + 0.3	V
Current drain per pin excluding V_{CC} and GND	I	10	mA
Operating temperature range	T_J	0 to +100	°C
Storage temperature	T_{STG}	-55 to +150	°C

Notes:
1. GND = 0 V, V_{CC} = 1.8 V ± 0.1 V, V_{CCH} = 3.3 V ± 0.3 V, T_J = 0×C to +100×C, CL = 50 pF
2. Absolute maximum ratings are stress ratings only, and functional operation at the maximum is not guaranteed. Stress beyond the maximum rating may affect device reliability or cause permanent damage to the device.
3. Power up sequence: During power up, and throughout the DSP56311 operation, V_{CCH} voltage must always be higher or equal to V_{CC} voltage.

THERMAL CHARACTERISTICS

Table 2-2. Thermal Characteristics

Characteristic	Symbol	PBGA[3] Value	PBGA[4] Value	Unit
Junction-to-ambient thermal resistance	$R_{\theta JA}$ or θ_{JA}	49	TBD	°C/W
Junction-to-case thermal resistance	$R_{\theta JC}$ or θ_{JC}	10	—	°C/W
Thermal characterization parameter	Ψ_{JT}	8	TBD	°C/W

Notes:
1. Junction-to-ambient thermal resistance is based on measurements on a horizontal single-sided printed circuit board per SEMI G38-87 in natural convection.(SEMI is Semiconductor Equipment and Materials International, 805 East Middlefield Rd., Mountain View, CA 94043, (415) 964-5111)
2. Junction-to-case thermal resistance is based on measurements using a cold plate per SEMI G30-88, with the exception that the cold plate temperature is used for the case temperature.
3. These are simulated values; testing is not complete. See note 1 for test board conditions.
4. These are simulated values; testing is not complete. The test board has two, 2-ounce signal layers and two 1-ounce solid ground planes internal to the test board.

DC ELECTRICAL CHARACTERISTICS

Table 2-3. DC Electrical Characteristics[6]

Characteristics	Symbol	Min	Typ	Max	Unit
Supply voltage	V_{CC}	1.7	1.8	1.9	V
Input/Output Supply Voltage	V_{CCH}	3.0	3.3	3.6	V
Input high voltage • All inputs except EXTAL • All inputs except EXTAL • EXTAL[8]	 V_{IH} V_{IHP} V_{IHX}	 2.0 2.0 $0.8 \times V_{CCH}$	 — — —	 $V_{CCH} + 0.4$ $V_{CCH} + 0.4$ V_{CCH}	 V V V
Input low voltage • D(0:23), $\overline{\text{BG}}$, $\overline{\text{BB}}$, $\overline{\text{TA}}$, MOD[1]/$\overline{\text{IRQ}}$[1], $\overline{\text{RESET}}$, PINIT • All JTAG/ESSI/SCI/Timer/HI08 pins • EXTAL[8]	 V_{IL} V_{ILP} V_{ILX}	 –0.3 –0.3 –0.3	 — — —	 0.8 0.8 $0.2 \times V_{CCH}$	 V V V
Input leakage current	I_{IN}	–10	—	10	µA
High impedance (off-state) input current (@ 2.4 V / 0.4 V)	I_{TSI}	–10	—	10	µA
Output high voltage • TTL (I_{OH} = –0.4 mA)[5,7] • CMOS (I_{OH} = –10 µA)[5]	V_{OH}	 2.4 $V_{CC} - 0.01$	 — —	 — —	 V V
Output low voltage • TTL (I_{OL} = 3.0 mA, open-drain pins I_{OL} = 6.7 mA)[5,7] • CMOS (I_{OL} = 10 µA)[5]	V_{OL}	 — —	 — —	 0.4 0.01	 V V
Internal supply current[2]: • In Normal mode • In Wait mode[3] • In Stop mode[4]	 I_{CCI} I_{CCW} I_{CCS}	 — — —	 150 MHz: 110 150 MHz: 7. 5 100	 — — —	 mA mA µA
PLL supply current		—	1	2.5	mA
Input capacitance[5]	C_{IN}	—	—	10	pF

Table 2-3. DC Electrical Characteristics[6] (Continued)

Characteristics	Symbol	Min	Typ	Max	Unit
Notes: 1. Refers to MODA/$\overline{\text{IRQA}}$, MODB/$\overline{\text{IRQB}}$, MODC/$\overline{\text{IRQC}}$, and MODD/$\overline{\text{IRQD}}$ pins 2. **Power Consumption Considerations** on page 4-3 provides a formula to compute the estimated current requirements in Normal mode. In order to obtain these results, all inputs must be terminated (that is, not allowed to float). Measurements are based on synthetic intensive DSP benchmarks (see **Appendix A**). The power consumption numbers in this specification are 90 percent of the measured results of this benchmark. This reflects typical DSP applications. Typical internal supply current is measured with V_{CCH} = 3.3 V, V_{CC} = 1.8 V at T_J = 100°C. 3. In order to obtain these results, all inputs must be terminated (that is, not allowed to float). PLL and XTAL signals are disabled during Stop state. 4. DC current in stop model is based on preliminary estimation, and will be evaluated based on measurements. In order to obtain these results, all inputs, which are not disconnected at Stop mode, must be terminated (that is, not allowed to float). 5. Periodically sampled and not 100 percent tested 6. V_{CCH} = 3.3 V ± 0.3 V, V_{CC} = 1.8 V ± 0.1 V; T_J = 0°C to +100 °C, C_L = 50 pF 7. This characteristic does not apply to XTAL and PCAP. 8. Driving EXTAL to the low V_{IHX} or the high V_{ILX} value may cause additional power consumption (DC current). To minimize power consumption, the minimum V_{IHX} should be no lower than $0.9 \times V_{CCH}$ and the maximum V_{ILX} should be no higher than $0.1 \times V_{CCH}$.					

AC ELECTRICAL CHARACTERISTICS

The timing waveforms shown in the AC electrical characteristics section are tested with a V_{IL} maximum of 0.3 V and a V_{IH} minimum of 2.4 V for all pins except EXTAL, which is tested using the input levels shown in **Note 6** of the previous table. AC timing specifications, which are referenced to a device input signal, are measured in production with respect to the 50 percent point of the respective input signal's transition. DSP56311 output levels are measured with the production test machine V_{OL} and V_{OH} reference levels set at 0.4 V and 2.4 V, respectively.

Note: Although the minimum value for the frequency of EXTAL is 0 MHz, the device AC test conditions are 15 MHz and rated speed.

INTERNAL CLOCKS

Table 2-4. Internal Clocks, ~~CLKOUT~~

Characteristics	Symbol	Expression[1, 2]		
		Min	**Typ**	**Max**
Internal operation frequency ~~and CLKOUT~~ with PLL enabled	f	—	(Ef × MF)/ (PDF × DF)	—
Internal operation frequency ~~and CLKOUT~~ with PLL disabled	f	—	Ef/2	—
Internal clock ~~and CLKOUT~~ high period • With PLL disabled • With PLL enabled and MF ≤ 4 • With PLL enabled and MF > 4	T_H	— 0.49 × ET_C × PDF × DF/MF 0.47 × ET_C × PDF × DF/MF	ET_C — —	— 0.51 × ET_C × PDF × DF/MF 0.53 × ET_C × PDF × DF/MF
Internal clock ~~and CLKOUT~~ low period • With PLL disabled • With PLL enabled and MF ≤ 4 • With PLL enabled and MF > 4	T_L	— 0.49 × ET_C × PDF × DF/MF 0.47 × ET_C × PDF × DF/MF	ET_C — —	— 0.51 × ET_C × PDF × DF/MF 0.53 × ET_C × PDF × DF/MF
Internal clock ~~and CLKOUT~~ cycle time with PLL enabled	T_C	—	ET_C × PDF × DF/MF	—
Internal clock ~~and CLKOUT~~ cycle time with PLL disabled	T_C	—	2 × ET_C	—
Instruction cycle time	I_{CYC}	—	T_C	—

Notes:
1. DF = Division Factor
   Ef = External frequency
   ET_C = External clock cycle
   MF = Multiplication Factor
   PDF = Predivision Factor
   T_C = internal clock cycle
2. See the **PLL and Clock Generation** section in the *DSP56300 Family Manual* for a detailed discussion of the PLL.

EXTERNAL CLOCK OPERATION

The DSP56311 system clock can be derived from the on–chip crystal oscillator, as shown in **Figure 1** on the cover page, or it can be externally supplied. An externally supplied square wave voltage source should connect to EXTAL (see **Figure 2-1**), leaving XTAL physically not connected to the board or socket.

Fundamental Frequency
Fork Crystal Oscillator

Suggested Component Values:

f_{OSC} = 32.768 kHz
R1 = 3.9 MΩ ± 10%
C = 22 pF ± 20%
R2 = 200 kΩ ± 10%

Calculations were done for a 32.768 kHz crystal with the following parameters:
a load capacitance (C_L) of 12.5 pF,
a shunt capacitance (C_0) of 1.8 pF,
a series resistance of 40 kΩ, and
a drive level of 1 µW.

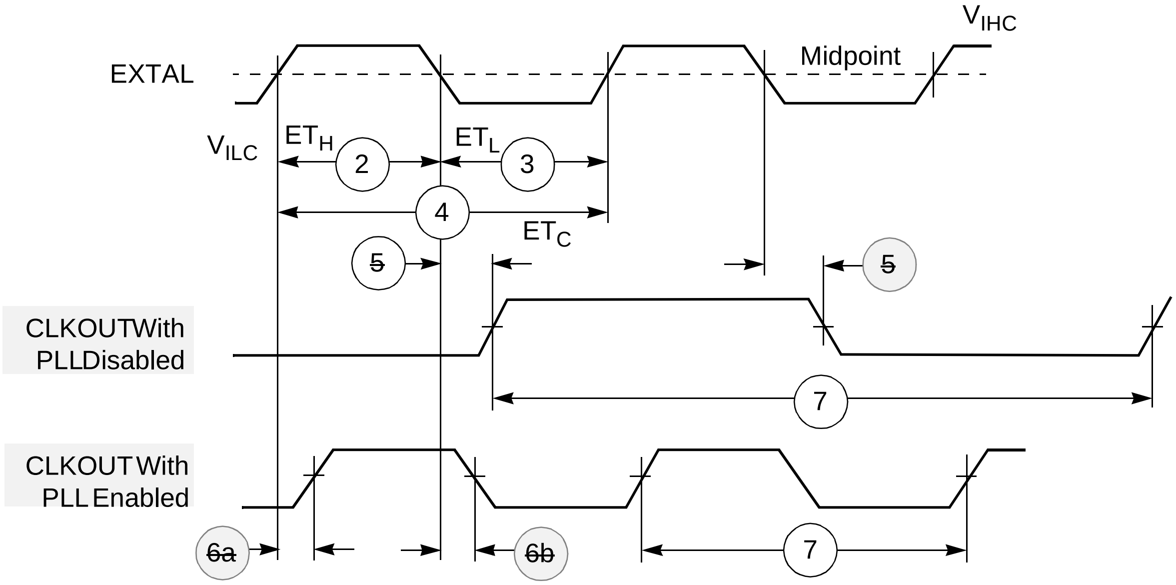
Fundamental Frequency
Crystal Oscillator

Suggested Component Values:

f_{OSC} = 4 MHz	f_{OSC} = 20 MHz
R = 680 kΩ ± 10%	R = 680 kΩ ± 10%
C = 56 pF ± 20%	C = 22 pF ± 20%

Calculations were done for a 4/20 MHz crystal with the following parameters:
a $C_L$of 30/20 pF,
a C_0 of 7/6 pF,
a series resistance of 100/20 Ω, and
a drive level of 2 mW.

Figure 2-1. Crystal Oscillator Circuits



Note: The midpoint is 0.5 (V_{IHC} + V_{ILC}).

Figure 2-2. External Clock Timing

Table 2-5. Clock Operation

No.	Characteristics	Symbol	150 MHz	
			Min	Max
1	Frequency of EXTAL (EXTAL Pin Frequency) The rise and fall time of this external clock should be 3 ns maximum.	Ef	0	150.0
2	EXTAL input high[1, 2] • With PLL disabled (46.7%–53.3% duty cycle[6]) • With PLL enabled (42.5%–57.5% duty cycle[6])	ET_H	3.11 ns 2.83 ns	∞ 78.5 µs
3	EXTAL input low[1, 2] • With PLL disabled (46.7%–53.3% duty cycle[6]) • With PLL enabled (42.5%–57.5% duty cycle[6])	ET_L	3.11 ns 2.83 ns	∞ 78.5 µs
4	EXTAL cycle time[2] • With PLL disabled • With PLL enabled	ET_C	6.67 ns 6.67 ns	∞ 136.5 µs
~~5~~	~~CLKOUT change from EXTAL fall with PLL disabled~~		~~4.3 ns~~	~~11.0 ns~~

Table 2-5. Clock Operation (Continued)

No.	Characteristics	Symbol	150 MHz	
			Min	Max
~~6~~	~~CLKOUT rising edge from EXTAL rising edge with PLL enabled (MF = 1, PDF = 1, Ef > 15 MHz)~~[3,5]		~~0.0 ns~~	~~1.8 ns~~
	~~CLKOUT falling edge from EXTAL rising edge with PLL enabled (MF = 2 or 4, PDF = 1, Ef > 15 MHz)~~[3,5]		~~0.0 ns~~	~~1.8 ns~~
	~~CLKOUT falling edge from EXTAL falling edge with PLL enabled (MF $\leq$ 4, PDF $\neq$ 1, Ef / PDF > 15 MHz)~~[3,5]		~~0.0 ns~~	~~1.8 ns~~
7	Instruction cycle time = $I_{CYC} = T_C$[4] (see **Figure 2-4**) (46.7%–53.3% duty cycle)	I_{CYC}		
	• With PLL disabled		13.33 ns	∞
	• With PLL enabled		6.7 ns	4266.7 ns

Notes:
1. Measured at 50 percent of the input transition
2. The maximum value for PLL enabled is given for minimum V_{CO} and maximum MF.
3. Periodically sampled and not 100 percent tested
4. The maximum value for PLL enabled is given for minimum V_{CO} and maximum DF.
5. ~~The skew is not guaranteed for any other MF value.~~
6. The indicated duty cycle is for the specified maximum frequency for which a part is rated. The minimum clock high or low time required for correction operation, however, remains the same at lower operating frequencies; therefore, at a lower clock frequency, the signal symmetry can vary from the specified duty cycle as long as the minimum high time and low time requirements are met.

PHASE LOCK LOOP (PLL) CHARACTERISTICS

Table 2-6. PLL Characteristics

Characteristics	150 MHz		Unit
	Min	Max	
V_{CO} frequency when PLL enabled ($MF \times E_f \times 2/PDF$)	30	300	MHz
PLL external capacitor (PCAP pin to V_{CCP}) (C_{PCAP}[1)])			
• @ MF $\leq$ 4	$(580 \times MF) - 100$	$(780 \times MF) - 140$	pF
• @ MF > 4	$830 \times MF$	$1470 \times MF$	pF

Note: C_{PCAP} is the value of the PLL capacitor (connected between the PCAP pin and V_{CCP}). The recommended value in pF for C_{PCAP} can be computed from one of the following equations:

$(680 \times MF) - 120$, for MF $\leq$ 4, or

$1100 \times MF$, for MF > 4.

RESET, STOP, MODE SELECT, AND INTERRUPT TIMING

	• $\overline{\mathrm{IRQ}}$, $\overline{\mathrm{NMI}}$ (edge trigger)	$3T_C$	—	20.0	ns

Table 2-7. Reset, Stop, Mode Select, and Interrupt Timing[6] (Continued)

No.	Characteristics	Expression	150 MHz		Unit
			Min	Max	
29	Delay from $\overline{\mathrm{IRQA}}$, $\overline{\mathrm{IRQB}}$, $\overline{\mathrm{IRQC}}$, $\overline{\mathrm{IRQD}}$, $\overline{\mathrm{NMI}}$ assertion to external memory (DMA source) access address out valid	$4.25 \times T_C + 2.0$	30.3	—	ns

Notes:
1. When fast interrupts are used and $\overline{\mathrm{IRQA}}$, $\overline{\mathrm{IRQB}}$, $\overline{\mathrm{IRQC}}$, and $\overline{\mathrm{IRQD}}$ are defined as level-sensitive, timings 19 through 21 apply to prevent multiple interrupt service. To avoid these timing restrictions, the deasserted Edge-triggered mode is recommended when fast interrupts are used. Long interrupts are recommended for Level-sensitive mode.
2. This timing depends on several settings:

   For PLL disable, using internal oscillator (PLL Control Register (PCTL) Bit 16 = 0) and oscillator disabled during Stop (PCTL Bit 17 = 0), a stabilization delay is required to assure that the oscillator is stable before programs are executed. In that case, resetting the Stop delay (OMR Bit 6 = 0) provides the proper delay. While OMR Bit 6 = 1 can be set, it is not recommended, and these specifications do not guarantee timings for that case.

   For PLL disable, using internal oscillator (PCTL Bit 16 = 0) and oscillator enabled during Stop (PCTL Bit 17=1), no stabilization delay is required and recovery is minimal (OMR Bit 6 setting is ignored).

   For PLL disable, using external clock (PCTL Bit 16 = 1), no stabilization delay is required and recovery time is defined by the PCTL Bit 17 and OMR Bit 6 settings.

   For PLL enable, if PCTL Bit 17 is 0, the PLL is shutdown during Stop. Recovering from Stop requires the PLL to get locked. The PLL lock procedure duration, PLL Lock Cycles (PLC), may be in the range of 0 to 1000 cycles. This procedure occurs in parallel with the stop delay counter, and stop recovery ends when the last of these two events occurs. The stop delay counter completes count or PLL lock procedure completion.

   PLC value for PLL disable is 0.

   The maximum value for ET_C is 4096 (maximum MF) divided by the desired internal frequency (that is, for 66 MHz it is 4096/66 MHz = 62 μs). During the stabilization period, T_C, $T_{H,}$ and T_L is not constant, and their width may vary, so timing may vary as well.
3. Periodically sampled and not 100 percent tested.
4. For an external clock generator, $\overline{\mathrm{RESET}}$ duration is measured while $\overline{\mathrm{RESET}}$ is asserted, V_{CC} is valid, and the EXTAL input is active and valid.

   For internal oscillator, $\overline{\mathrm{RESET}}$ duration is measured while $\overline{\mathrm{RESET}}$ is asserted and V_{CC} is valid. The specified timing reflects the crystal oscillator stabilization time after power-up. This number is affected both by the specifications of the crystal and other components connected to the oscillator and reflects worst case conditions.

   When the V_{CC} is valid, but the other “required $\overline{\mathrm{RESET}}$ duration” conditions (as specified above) have not been yet met, the device circuitry is in an uninitialized state that can result in significant power consumption and heat-up. Designs should minimize this state to the shortest possible duration.
5. If PLL does not lose lock.
6. $V_{CCH} = 3.3\ \mathrm{V} \pm 0.3\ \mathrm{V}$, $V_{CC} = 1.8\ \mathrm{V} \pm 0.1\ \mathrm{V}$; $T_J = 0°\mathrm{C}$ to $+100°\mathrm{C}$, $C_L = 50\ \mathrm{pF}$
7. WS = number of wait states (measured in clock cycles, number of T_C).
8. Use expression to compute maximum value.

119	$\overline{\text{TA}}$ hold after $\overline{\text{RD}}$ or $\overline{\text{WR}}$ deassertion	—		0	—	ns

Notes:
1. WS is the number of wait states specified in the BCR. The value is given for the minimum for a given category. (for example, for a category of $[2 \leq WS \leq 7]$ timing is specified for 2 wait states.) Two wait states is the minimum otherwise.
2. Timings 100 and107 are guaranteed by design, not tested.
3. All timings for 150 MHz are measured from $0.5 \cdot V_{CCH}$ to $0.5 \cdot V_{CCH}$.
4. For $\overline{\text{TA}}$ negation: timing 118 is relative to the deassertion edge of $\overline{\text{RD}}$ or $\overline{\text{WR}}$ were $\overline{\text{TA}}$ to remain active.

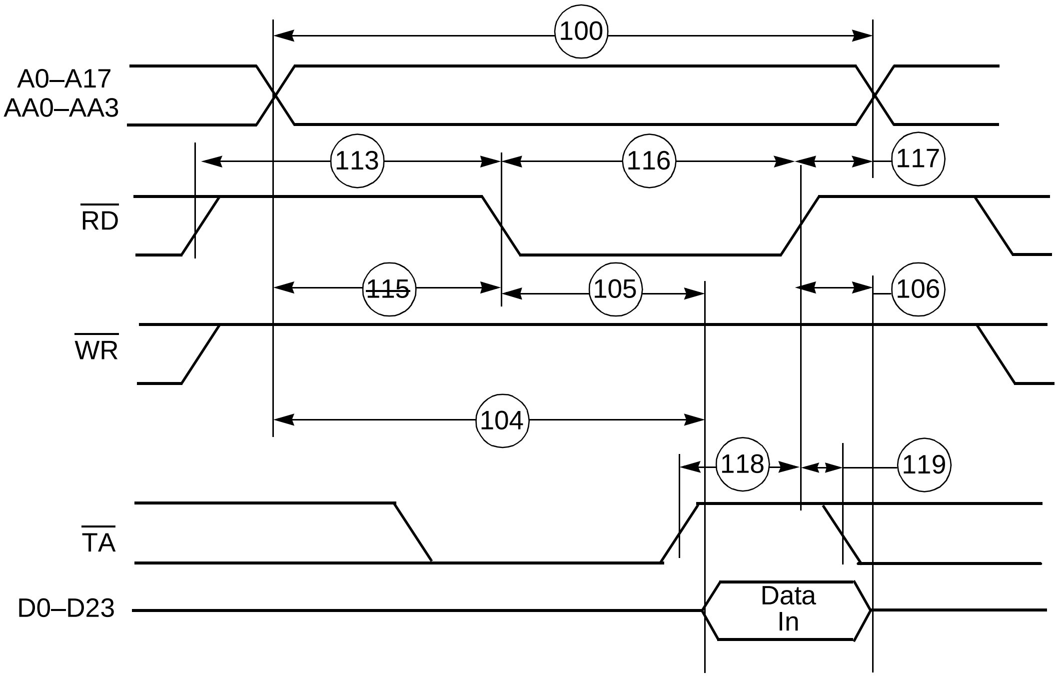

Figure 2-12. SRAM Read Access

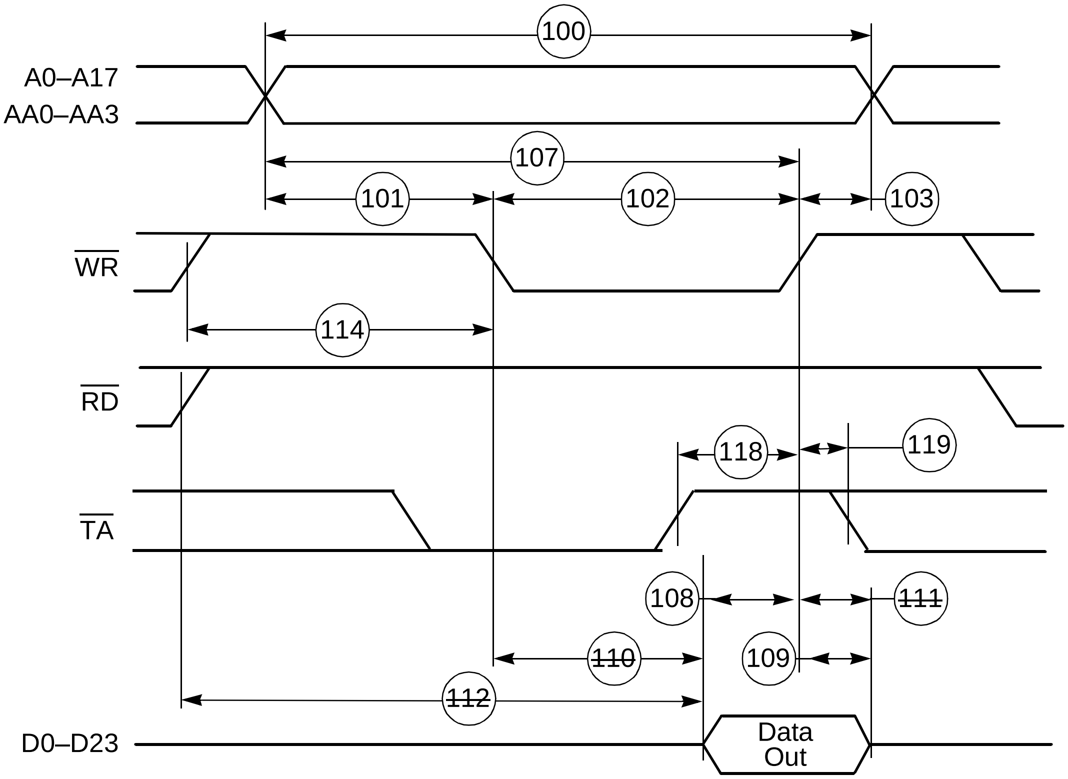

Figure 2-13. SRAM Write Access

Arbitration Timings

Table 2-9. Asynchronous Bus Arbitration timing

No.	Characteristics	Expression	150 MHz		Unit
			Min	Max	
250	$\overline{\text{BB}}$ assertion window from $\overline{\text{BG}}$ input negation.	2.5 × Tc + 5	—	22	ns
251	Delay from $\overline{\text{BB}}$ assertion to $\overline{\text{BG}}$ assertion	2 × Tc + 5	18.3	—	ns
Comments: 1. Bit 13 in the OMR register must be set to enable Asynchronous Arbitration mode. 2. At 150 MHz, Asynchronous Arbitration mode is recommended. 3. To guarantee timings 250 and 251, it is recommended to assert $\overline{\text{BG}}$ inputs to different DSP56300 devices (on the same bus) in a non-overlap manner, as shown in **Figure 2-14**, where BG1 is the $\overline{\text{BG}}$ signal for one DSP56300 device while BG2 is the BG signal for a second DSP56300 device.					

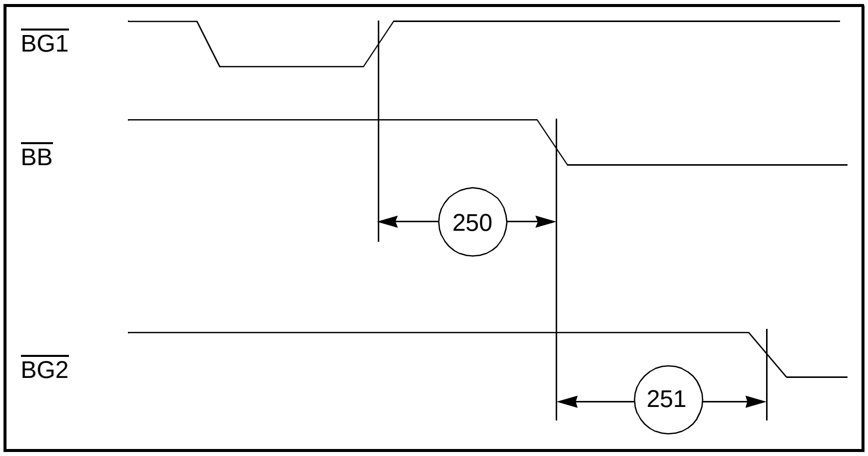

Figure 2-14. Asynchronous Bus Arbitration Timing

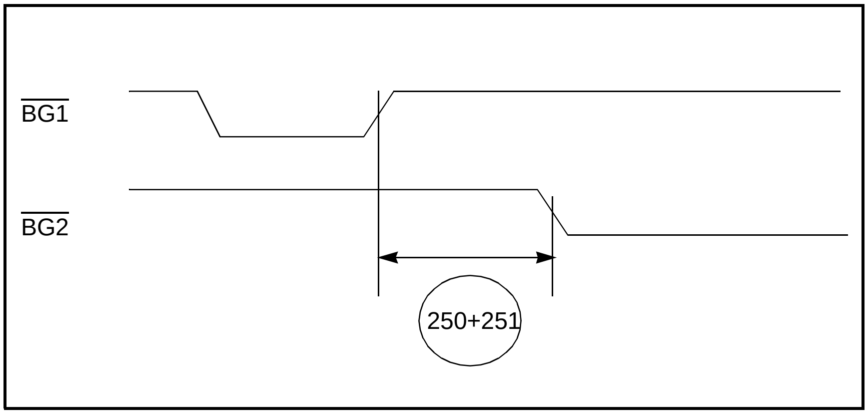

Figure 2-15. Asynchronous Bus Arbitration Timing

The asynchronous bus arbitration is enabled by internal synchronization circuits on $\overline{\mathrm{BG}}$, and $\overline{\mathrm{BB}}$ inputs. These synchronization circuits add delay from the external signal until it is exposed to internal logic. As a result of this delay, a DSP56300 part may assume mastership and assert $\overline{\mathrm{BB}}$, for some time after $\overline{\mathrm{BG}}$ is negated. This is the reason for timing 250.

Once $\overline{\mathrm{BB}}$ is asserted, there is a synchronization delay from $\overline{\mathrm{BB}}$ assertion to the time this assertion is exposed to other DSP56300 components that are potential masters on the same bus. If $\overline{\mathrm{BG}}$ input is asserted before that time, and $\overline{\mathrm{BG}}$ is asserted and $\overline{\mathrm{BB}}$ is negated, another DSP56300 component may assume mastership at the same time. Therefore, some non-overlap period between one $\overline{\mathrm{BG}}$ input active to another $\overline{\mathrm{BG}}$ input active is required. Timing 251 ensures that overlaps are avoided.

HOST INTERFACE TIMING

Table 2-10. Host Interface Timing[1, 2, 12]

337	A10–A8 (HMUX=1), A2–A0 (HMUX=0), HR/$\overline{\text{W}}$ hold time after data strobe deassertion[4]		3.3	—	ns
338	Delay from read data strobe deassertion to host request assertion for “Last Data Register” read[5, 7, 8]	2 × T_C + 20.6	34.0	—	ns

Table 2-10. Host Interface Timing[1, 2, 12] (Continued)

No.	Characteristic[10]	Expression	150 MHz		Unit
			Min	Max	
339	Delay from write data strobe deassertion to host request assertion for “Last Data Register” write[6, 7, 8]	$1.5 \times T_C + 16.5$	26.5	—	ns
340	Delay from data strobe assertion to host request deassertion for “Last Data Register” read or write (HROD=0)[4, 7, 8]		—	20.24	ns
341	Delay from data strobe assertion to host request deassertion for “Last Data Register” read or write (HROD=1, open drain host request)[4, 7, 8, 9]		—	300.0	ns

Notes:
1. See the Programmer’s Model section in the chapter on the HI08 in the *DSP56311 User’s Manual*.
2. In the timing diagrams below, the controls pins are drawn as active low. The pin polarity is programmable.
3. This timing is applicable only if two consecutive reads from one of these registers are executed.
4. The data strobe is Host Read (HRD) or Host Write (HWR) in the Dual Data Strobe mode and Host Data Strobe (HDS) in the Single Data Strobe mode.
5. The read data strobe is HRD in the Dual Data Strobe mode and HDS in the Single Data Strobe mode.
6. The write data strobe is HWR in the Dual Data Strobe mode and HDS in the Single Data Strobe mode.
7. The host request is HREQ in the Single Host Request mode and HRRQ and HTRQ in the Double Host Request mode.
8. The “Last Data Register” is the register at address $7, which is the last location to be read or written in data transfers. This is RXL/TXL in the Little Endian mode (HBE = 0), or RXH/TXH in the Big Endian mode (HBE = 1).
9. In this calculation, the host request signal is pulled up by a 4.7 kΩ resistor in the Open-drain mode.
10. $V_{CCH} = 3.3\ V \pm 0.3\ V$, $V_{CC} = 1.8\ V \pm 0.1\ V$; $T_J = 0°C$ to $+100\ °C$, $C_L = 50\ pF$
11. This timing is applicable only if a read from the “Last Data Register” is followed by a read from the RXL, RXM, or RXH registers without first polling RXDF or HREQ bits, or waiting for the assertion of the HREQ signal.
12. After the external host writes a new value to the ICR, the HI08 will be ready for operation after three DSP clock cycles ($3 \times Tc$).

Table 2-12. ESSI Timings (Continued)

No.	Characteristics[4, 6, 7]	Symbol	Expression	150 MHz		Cond-ition[5]	Unit
				Min	Max		

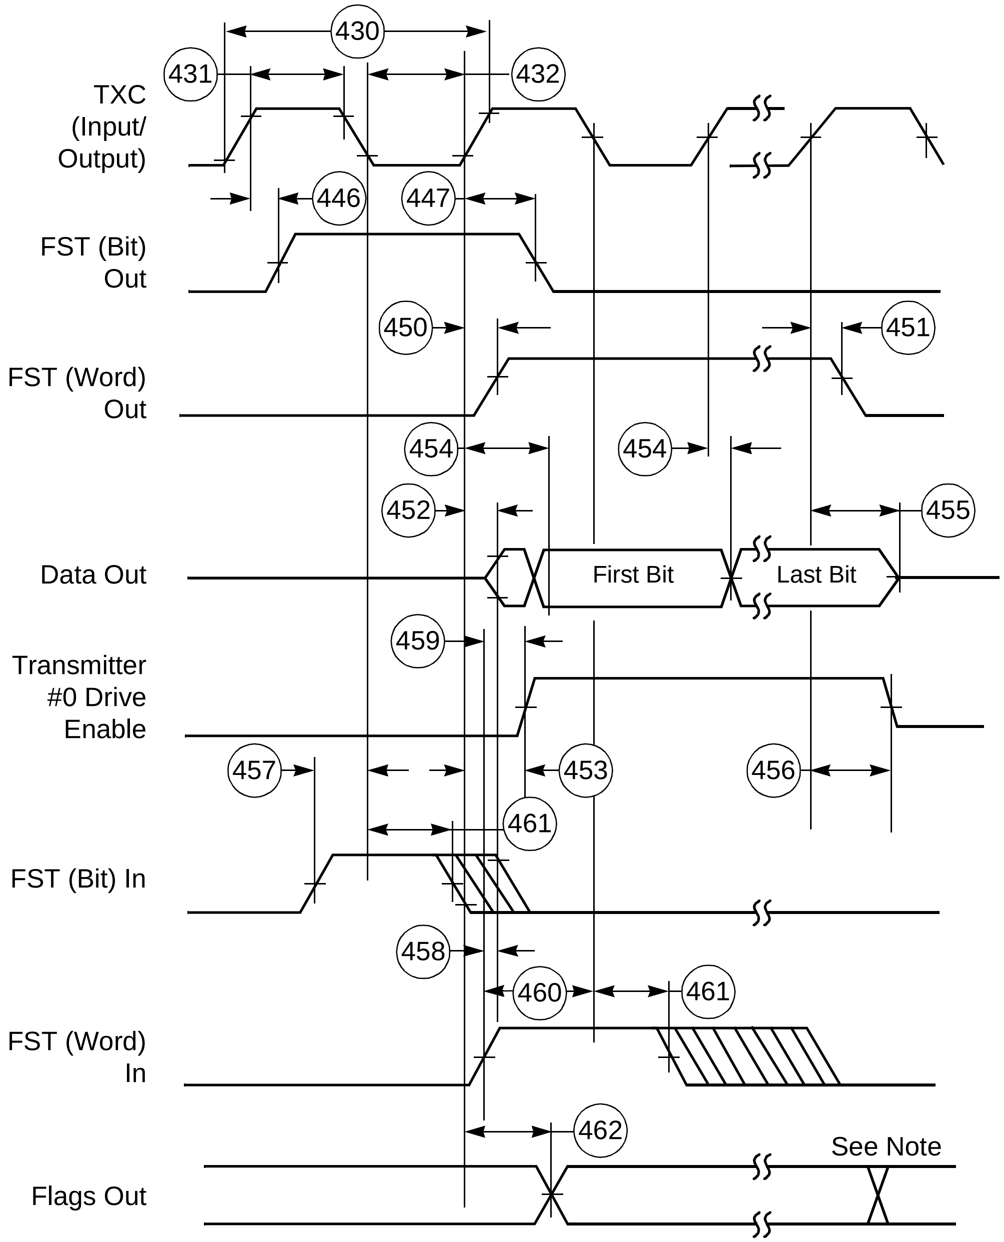
Notes:
1. For the internal clock, the external clock cycle is defined by Icyc and the ESSI control register.
2. The word-relative frame sync signal waveform relative to the clock operates in the same manner as the bit-length frame sync signal waveform, but spreads from one serial clock before first bit clock (same as Bit Length Frame Sync signal), until the one before last bit clock of the first word in frame.
3. Periodically sampled and not 100 percent tested
4. V_{CCH} = 3.3 V ± 0.3 V, V_{CC} = 1.8 V ± 0.1 V; T_J = 0°C to +100 °C, C_L = 50 pF
5. TXC (SCK Pin) = Transmit Clock
   RXC (SC0 or SCK Pin) = Receive Clock
   FST (SC2 Pin) = Transmit Frame Sync
   FSR (SC1 or SC2 Pin) Receive Frame Sync
6. i ck = Internal Clock
   x ck = External Clock
   i ck a = Internal Clock, Asynchronous Mode
   (Asynchronous implies that TXC and RXC are two different clocks)
   i ck s = Internal Clock, Synchronous Mode
   (Synchronous implies that TXC and RXC are the same clock)
7. bl = bit length
   wl = word length
   wr = word length relative



Note: In Network mode, output flag transitions can occur at the start of each time slot within the frame. In Normal mode, the output flag state is asserted for the entire frame period.

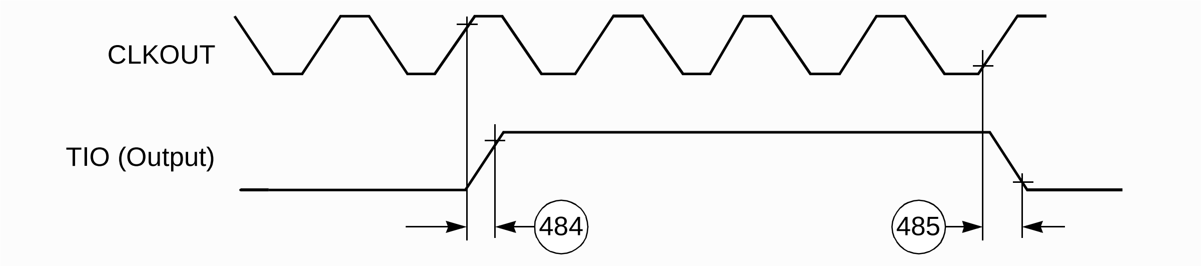

Figure 2-27. External Pulse Generation

CONSIDERATIONS FOR GPIO USE

The following considerations can be helpful when GPIO is used for output or input.

GPIO as Output

When you use a GPIO pin as an output, note that:

- The time from fetch of the instruction that changes the GPIO pin to the actual change is 7 core clock cycles. This is true, assuming that the instruction is a on- cycle instruction and that there are no pipeline stalls or any other pipeline delays.
- The maximum rise or fall time of a GPIO pin is 13ns (TTL levels, assuming that the maximum of 50 pF load limit is met).

GPIO as Input

GPIO inputs are not synchronized with the core clock. When only one GPIO bit is polled, this lack of synchronization presents no problem, since the read value can be either the previous value or the new value of the corresponding GPIO pin. However, there is the risk of reading an intermediate state if:

- Two or more GPIO bits are treated as a coupled group (for example, four possible status states encoded in two bits) and
- The read operation occurs during a simultaneous change of GPIO pins (for example, the change of 00 to 11 may happen through an intermediate state of 01 or 10).

Therefore, when GPIO bits are read, the recommended practice is to poll continuously until two consecutive read operations have identical results.

JTAG TIMING

Table 2-14. JTAG Timing

No.	Characteristics	All frequencies		Unit
		Min	Max	
500	TCK frequency of operation	0.0	22.0	MHz
501	TCK cycle time in Crystal mode	45.0	—	ns
502	TCK clock pulse width measured at 1.5 V	20.0	—	ns
503	TCK rise and fall times	0.0	3.0	ns
504	Boundary scan input data setup time	5.0	—	ns
505	Boundary scan input data hold time	24.0	—	ns
506	TCK low to output data valid	0.0	40.0	ns
507	TCK low to output high impedance	0.0	40.0	ns
508	TMS, TDI data setup time	5.0	—	ns
509	TMS, TDI data hold time	25.0	—	ns
510	TCK low to TDO data valid	0.0	44.0	ns
511	TCK low to TDO high impedance	0.0	44.0	ns
512	$\overline{\text{TRST}}$ assert time	100.0	—	ns
513	$\overline{\text{TRST}}$ setup time to TCK low	40.0	—	ns

Notes:
1. V_{CCH} = 3.3 V ± 0.3 V, V_{CC} = 1.8 V ± 0.1 V; T_J = 0°C to +100 °C, C_L = 50 pF
2. All timings apply to OnCE module data transfers because it uses the JTAG port as an interface.

SECTION 3

PACKAGING

PIN-OUT AND PACKAGE INFORMATION

This section provides information on the package for the DSP56311, including diagrams of the package pinouts and tables describing how the signals described in **Section 1** are allocated for the package.

The DSP56311 is available in a 196-pin Plastic Ball Grid Array (PBGA) package.

PBGA Package Description

Top and bottom views of the PBGA package are shown in **Figure 3-1.** and **Figure 3-2.** with their pin-outs.

Note: Signal names are based on configured functionality. Most connections supply a single signal. Some connections provide a signal with dual functionality, such as the MODx/$\overline{\text{IRQx}}$ pins that select an operating mode after $\overline{\text{RESET}}$ is deasserted but act as interrupt lines during operation. Some signals have configurable polarity; these names are shown with and without overbars, such as $\overline{\text{HAS}}$/HAS. Some connections have two or more configurable functions; names assigned to these connections indicate the function for a specific configuration. For example, connection N2 is data line H7 in non-multiplexed bus mode, data/address line HAD7 in multiplexed bus mode, or GPIO line PB7 when the GPIO function is enabled for this pin. Unlike the TQFP package, most of the GND pins are connected internally in the center of the connection array and act as heat sink for the chip. Therefore, except for GND_{P} and GND_{P1} that support the PLL, other GND signals do not support individual subsystems in the chip.

Figure 3-3. DSP56311 Mechanical Information, 196-pin PBGA Package

ORDERING DRAWINGS

Complete mechanical information on DSP56311 packaging is available by facsimile through Motorola's Mfax system. Call the following number to obtain information by facsimile:

(602) 244-6609

The Mfax automated system requests the following information:

- The receiving facsimile telephone number including area code or country code
- The caller's personal identification number (PIN)

Note: For first time callers, the system provides instructions for setting up a PIN, which requires entry of a name and telephone number.

- The type of information requested:
  - Instructions for using the system
  - A literature order form
  - Specific part technical information or data sheets
  - Other information described by the system messages

A total of three documents can be ordered per call.

The DSP56311 196-pin PBGA package mechanical drawing is referenced as 1128-01.

SECTION 4

DESIGN CONSIDERATIONS

THERMAL DESIGN CONSIDERATIONS

An estimate of the chip junction temperature, T_J, in °C can be obtained from this equation:

Equation 1: $T_J = T_A + (P_D \times R_{\theta JA})$

Where:

T_A = ambient temperature °C
$R_{\theta JA}$ = package junction-to-ambient thermal resistance °C/W
P_D = power dissipation in package

Historically, thermal resistance has been expressed as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance, as in this equation:

Equation 2: $R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$

Where:

$R_{\theta JA}$ = package junction-to-ambient thermal resistance °C/W
$R_{\theta JC}$ = package junction-to-case thermal resistance °C/W
$R_{\theta CA}$ = package case-to-ambient thermal resistance °C/W

$R_{\theta JC}$ is device-related and cannot be influenced by the user. The user controls the thermal environment to change the case-to-ambient thermal resistance, $R_{\theta CA}$. For example, the user can change the air flow around the device, add a heat sink, change the mounting arrangement on the printed circuit board (PCB) or otherwise change the thermal dissipation capability of the area surrounding the device on a PCB. This model is most useful for ceramic packages with heat sinks; some 90 percent of the heat flow is dissipated through the case to the heat sink and out to the ambient environment. For ceramic packages, in situations where the heat flow is split between a path to the case and an alternate path through the PCB, analysis of the device thermal performance may need the additional modeling capability of a system-level thermal simulation tool.

The thermal performance of plastic packages is more dependent on the temperature of the PCB to which the package is mounted. Again, if the estimates obtained from $R_{\theta JA}$ do not satisfactorily answer whether the thermal performance is adequate, a system-level model may be appropriate.

A complicating factor is the existence of three common ways to determine the junction-to-case thermal resistance in plastic packages.

- To minimize temperature variation across the surface, the thermal resistance is measured from the junction to the outside surface of the package (case) closest to the chip mounting area when that surface has a proper heat sink.
- To define a value approximately equal to a junction-to-board thermal resistance, the thermal resistance is measured from the junction to the point at which the leads attach to the case.
- If the temperature of the package case (T_T) is determined by a thermocouple, thermal resistance is computed from the value obtained by the equation $(T_J - T_T)/P_D$.

As noted earlier, the junction-to-case thermal resistances quoted in this data sheet are determined using the first definition. From a practical standpoint, that value is also suitable to determine the junction temperature from a case thermocouple reading in forced convection environments. In natural convection, the use of the junction-to-case thermal resistance to estimate junction temperature from a thermocouple reading on the case of the package will yield an estimate of a junction temperature slightly higher than actual temperature. Hence, the new thermal metric, thermal characterization parameter or Ψ_{JT}, has been defined to be $(T_J - T_T)/P_D$. This value gives a better estimate of the junction temperature in natural convection when the surface temperature of the package is used. Remember that surface temperature readings of packages are subject to significant errors caused by inadequate attachment of the sensor to the surface and to errors caused by heat loss to the sensor. The recommended technique is to attach a 40-gauge thermocouple wire and bead to the top center of the package with thermally conductive epoxy.

ELECTRICAL DESIGN CONSIDERATIONS

CAUTION

This device contains protective circuitry to guard against damage due to high static voltage or electrical fields. However, normal precautions are advised to avoid application of any voltages higher than maximum rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (for example, either GND or V_{CC}).

Use the following list of recommendations to insure correct DSP operation.

- Provide a low-impedance path from the board power supply to each V_{CC} pin on the DSP and from the board ground to each GND pin.
- Use at least six 0.01–0.1 μF bypass capacitors positioned as close as possible to the four sides of the package to connect the V_{CC} power source to GND.
- Ensure that capacitor leads and associated printed circuit traces that connect to the chip V_{CC} and GND pins are less than 0.5 inch per capacitor lead.
- Use at least a four-layer PCB with two inner layers for V_{CC} and GND.
- Because the DSP output signals have fast rise and fall times, PCB trace lengths should be minimal. This recommendation particularly applies to the address and data buses as well as the $\overline{\mathrm{IRQA}}$, $\overline{\mathrm{IRQB}}$, $\overline{\mathrm{IRQC}}$, $\overline{\mathrm{IRQD}}$, $\overline{\mathrm{TA}}$, and $\overline{\mathrm{BG}}$ pins. Maximum PCB trace lengths on the order of 6 inches are recommended.
- Consider all device loads as well as parasitic capacitance due to PCB traces when you calculate capacitance. This is especially critical in systems with higher capacitive loads that could create higher transient currents in the V_{CC} and GND circuits.
- All inputs must be terminated (that is, not allowed to float) by CMOS levels except for the three pins with internal pull-up resistors ($\overline{\mathrm{TRST}}$, TMS, $\overline{\mathrm{DE}}$).
- Take special care to minimize noise levels on the V_{CCP}, GND_P, and GND_{P1} pins.
- The following pins must be asserted after power-up: $\overline{\mathrm{RESET}}$ and $\overline{\mathrm{TRST}}$.
- If multiple DSP devices are on the same board, check for cross-talk or excessive spikes on the supplies due to synchronous operation of the devices.
- RESET must be asserted when the chip is powered up. A stable EXTAL signal should be supplied before deassertion of RESET.

POWER CONSUMPTION CONSIDERATIONS

Power dissipation is a key issue in portable DSP applications. Some of the factors affecting current consumption are described in this section. Most of the current consumed by CMOS devices is alternating current (ac), which is charging and discharging the capacitances of the pins and internal nodes.

Current consumption is described by this formula:

Equation 3: $I = C \times V \times f$

Where:

C = node/pin capacitance
V = voltage swing
f = frequency of node/pin toggle

Example 4-1. Current Consumption

For a Port A address pin loaded with 50 pF capacitance, operating at 3.3 V, with a 66 MHz clock, toggling at its maximum possible rate (33 MHz), the current consumption is expressed in this equation:

Equation 4: $$I = 50 \times 10^{-12} \times 3.3 \times 33 \times 10^{6} = 5.48 \text{ mA}$$

The maximum internal current (I_{CCI}max) value reflects the typical possible switching of the internal buses on best-case operation conditions—not necessarily a real application case. The typical internal current (I_{CCItyp}) value reflects the average switching of the internal buses on typical operating conditions.

Perform the following steps for applications that require very low current consumption:

1. Set the EBD bit when you are not accessing external memory.
2. Minimize external memory accesses, and use internal memory accesses.
3. Minimize the number of pins that are switching.
4. Minimize the capacitive load on the pins.
5. Connect the unused inputs to pull-up or pull-down resistors.
6. Disable unused peripherals.
7. Disable unused pin activity (for example, CLKOUT, XTAL).

One way to evaluate power consumption is to use a current-per-MIPS measurement methodology to minimize specific board effects (that is, to compensate for measured board current not caused by the DSP). A benchmark power consumption test algorithm is listed in **Appendix A**. Use the test algorithm, specific test current measurements, and the following equation to derive the current-per-MIPS value.

Equation 5: $$I / MIPS = I / MHz = (I_{typF2} - I_{typF1}) / (F2 - F1)$$

Where:

I_{typF2} = current at F2
I_{typF1} = current at F1
F2 = high frequency (any specified operating frequency)
F1 = low frequency (any specified operating frequency lower than F2)

Note: F1 should be significantly less than F2. For example, F2 could be 66 MHz and F1 could be 33 MHz. The degree of difference between F1 and F2 determines the amount of precision with which the current rating can be determined for an application.

PLL PERFORMANCE ISSUES

The following explanations should be considered as general observations on expected PLL behavior. There is no test that replicates these exact numbers. These observations were measured on a limited number of parts and were not verified over the entire temperature and voltage ranges.

~~Phase Skew Performance~~

~~The phase skew of the PLL is defined as the time difference between the falling edges of EXTAL and CLKOUT for a given capacitive load on CLKOUT over the entire process, temperature, and voltage ranges. As defined in **Figure 2-2.** on page 2-7for input frequencies greater than 15 MHz and the MF ≤ 4, this skew is greater than or equal to 0.0 ns and less than 1.8 ns; otherwise, this skew is not guaranteed. However, for MF < 10 and input frequencies greater than 10 MHz, this skew is between –1.4 ns and +3.2 ns.~~

~~Phase Jitter Performance~~

~~The phase jitter of the PLL is defined as the variations in the skew between the falling edges of EXTAL and CLKOUT for a given device in specific temperature, voltage, input frequency, MF, and capacitive load on CLKOUT. These variations are a result of the PLL locking mechanism. For input frequencies greater than 15 MHz and MF ≤ 4, this jitter is less than ±0.6 ns; otherwise, this jitter is not guaranteed. However, for MF < 10 and input frequencies greater than 10 MHz, this jitter is less than ±2 ns.~~

~~Frequency Jitter Performance~~

~~The frequency jitter of the PLL is defined as the variation of the frequency of CLKOUT. For small MF (MF < 10) this jitter is smaller than 0.5 percent. For mid-range MF (10 < MF < 500) this jitter is between 0.5 percent and approximately 2 percent. For large MF (MF > 500), the frequency jitter is 2–3 percent.~~

Input (EXTAL) Jitter Requirements

The allowed jitter on the frequency of EXTAL is 0.5 percent. If the rate of change of the frequency of EXTAL is slow (that is, it does not jump between the minimum and maximum values in one cycle) or the frequency of the jitter is fast (that is, it does not stay at an extreme value for a long time), then the allowed jitter can be 2 percent. The phase and frequency jitter performance results are valid only if the input jitter is less than the prescribed values.

APPENDIX A

POWER CONSUMPTION BENCHMARK

The following benchmark program evaluates DSP power use in a test situation. It enables the PLL, disables the external clock, and uses repeated multiply-accumulate (MAC) instructions with a set of synthetic DSP application data to emulate intensive sustained DSP operation.
